Disclaimer

This document aims to combine a review of the best available evidence with current clinical and expert practice. It is designed to provide information based on the best evidence available at the time of publication to assist in decision-making. The members of the Infection Control Guidelines Steering Committee, the Australian Commission for Safety and Quality in Health Care and the National Health and Medical Research Council give no warranty that the information contained in this document and any online updates available on the NHMRC website is correct or complete.

Infection prevention and control guidelines are necessarily general and are not intended to be a substitute for a healthcare professional’s judgment in each case. The members of the Infection Control Guidelines Steering Committee, the Australian Commission for Safety and Quality in Health Care and the National Health and Medical Research Council shall not be liable for any loss whatsoever whether due to negligence or otherwise arising from the use of or reliance on this document.

This document can be downloaded from the NHMRC website: http://www.nhmrc.gov.au
## Contents

Summary of recommendations ................................................. 1

Introduction ............................................................................. 7

**PART A  BASICS OF INFECTION PREVENTION AND CONTROL  15**

A1 Infection prevention and control in the healthcare setting ........... 17
  A1.1 Risks of contracting a healthcare-associated infection ................. 17
  A1.2 Standard and transmission-based precautions .......................... 21

A2 Overview of risk management in infection prevention and control ... 23
  A2.1 Risk-management basics ............................................... 23
  A2.2 Risk-management process .............................................. 25

A3 A patient-centred approach .................................................... 29
  A3.1 Patient-centred health care .............................................. 29
  A3.2 How does patient-centred care relate to infection prevention and control? .............................................. 30

**PART B  STANDARD AND TRANSMISSION-BASED PRECAUTIONS  31**

B1 Standard precautions .......................................................... 33
  B1.1 Hand hygiene .................................................................. 34
  B1.2 Personal protective equipment ......................................... 46
  B1.3 Handling and disposing of sharps ..................................... 62
  B1.4 Routine management of the physical environment ............... 68
  B1.5 Reprocessing of reusable instruments and equipment .......... 78
  B1.6 Respiratory hygiene and cough etiquette ............................ 84
  B1.7 Aseptic technique .......................................................... 85
  B1.8 Waste management ........................................................ 89

Summary of recommendations

These guidelines provide recommendations that outline the critical aspects of infection prevention and control. The recommendations were developed using the best available evidence and consensus methods by the Infection Control Steering Committee. They have been prioritised as key areas to prevent and control infection in a healthcare facility. It is recognised that the level of risk may differ according to the different types of facility and therefore some recommendations should be justified by risk assessment. When implementing these recommendations all healthcare facilities need to consider the risk of transmission of infection and implement according to their specific setting and circumstances.

The recommendations should be read in the context of the evidence base. This is discussed in Sections B1, B2 and B3, which also include advice on the practical application of the recommendations. The table below lists recommendations and the section of the guidelines in which they are discussed.

<tbody>
<tr>
<td>Multi-resistant organisms (MROs) (see Section B3)</td>
<td>Section B3.1.2 Page 113</td>
</tr>
</tbody>
</table>

#### 24 Implementation of core strategies in the control of MROs (MRSA, MRGN, VRE)

Implement transmission-based precautions for all patients colonised or infected with a multi-resistant organism, including:

- performing hand hygiene and putting on gloves and gowns before entering the patient-care area
- using patient-dedicated or single-use non-critical patient-care equipment
- using a single-patient room or, if unavailable, cohorting patients with the same strain of multi-resistant organism in designated patient-care areas
- ensuring consistent cleaning and disinfection of surfaces in close proximity to the patient and those likely to be touched by the patient and healthcare workers.

---

### Finding information

These recommendations provide the basis for appropriate infection prevention and control practice in the healthcare setting. Practical guidance on their implementation is given in Part B of these guidelines. The following table provides a directory for this guidance.

Introduction

Effective infection prevention and control is central to providing high quality health care for patients and a safe working environment for those that work in healthcare settings.

**Healthcare-associated infection is preventable**

There are around 200,000 healthcare-associated infections (HAIs) in Australian acute healthcare facilities each year\(^2\). This makes HAIs the most common complication affecting patients in hospital. As well as causing unnecessary pain and suffering for patients and their families, these adverse events prolong hospital stays and are costly to the health system. The problem does not just affect patients and workers in hospitals—HAIs can occur in any healthcare setting, including office-based practices (e.g. general practice clinics, dental clinics) and long-term care facilities (see Glossary). Any person working in or entering a healthcare facility is at risk. However, healthcare-associated infection is a potentially preventable adverse event rather than an unpredictable complication. It is possible to significantly reduce the rate of HAIs through effective infection prevention and control.

**Infection prevention and control is everybody's business**

Understanding the modes of transmission of infectious organisms and knowing how and when to apply the basic principles of infection prevention and control is critical to the success of an infection control program. This responsibility applies to everybody working and visiting a healthcare facility, including administrators, staff, patients and carers.

Successful approaches for preventing and reducing harms arising from HAIs involve applying a risk-management framework to manage ‘human’ and ‘system’ factors associated with the transmission of infectious agents. This approach ensures that infectious agents, whether common (e.g. gastrointestinal viruses) or evolving (e.g. influenza or multi-resistant organisms [MROs]), can be managed effectively.

**Development of the guidelines**

As part of the Australian Commission on Safety and Quality in Health Care’s (ACSQHC) HAIs priority program, the National Health and Medical Research Council (NHMRC) was asked to develop national guidelines that would provide a coordinated approach to the prevention and management of HAI. The NHMRC appointed an expert group to guide the development process (Steering Committee membership and terms of reference are given in Appendix 1). The guidelines are based on the best available evidence. They build on existing guidelines and reviews, as well as systematic reviews of the evidence.

**Aim**

By assisting healthcare workers to improve the quality of the care they deliver, these guidelines aim to promote and facilitate the overall goal of infection prevention and control:

*The creation of safe healthcare environments through the implementation of practices that minimise the risk of transmission of infectious agents.*

---

Introduction

Scope

The scope of these guidelines was established, following an initial period of consultation that included forums involving a wide range of stakeholders (see Appendix 2).

The guidelines were developed to establish a nationally accepted approach to infection prevention and control, focusing on core principles and priority areas for action. They provide a basis for healthcare workers and healthcare facilities to develop detailed protocols and processes for infection prevention and control specific to local settings.

This approach is underpinned by a risk-management framework to ensure the basic principles of infection prevention and control can be applied to a wide range of healthcare settings including office-based practice, long-term care facilities, remote area health services, home and community nursing and emergency services.

The evidence base for the guidelines addresses the highest level of risk of infection transmission in the healthcare setting, and has predominantly been drawn from the acute-care setting. However, case studies giving examples of risk assessments have been included to help illustrate how these recommendations can be applied to other settings.

Supporting documents have been developed for healthcare workers, patients and health facility managers to assist with implementation of the guidelines. These materials will be available on the NHMRC website.

The guidelines make reference to but do not include detailed information on:
- infectious diseases
- pandemic planning
- the reprocessing of reusable medical instruments or devices
- occupational health and safety
- hospital hotel services such as food services, laundry services or waste disposal
- engineering/health facility design.

The guidelines do not duplicate information provided in existing Australian Standards but refer to specific standards wherever relevant.

Target audience

The guidelines are for use by all those working in healthcare—this includes healthcare workers, management and support staff.

Evidence base

These guidelines are based on the best available evidence and knowledge of the practicalities of clinical procedures. They draw from other work in this area, including the two previous national infection control guidelines, international infection control guidelines, systematic literature reviews conducted to inform the development of these guidelines, work on HAI prevention from ACSQHC, national discipline-based infection control guidelines, and Australian Standards relevant to infection prevention and control. Australian data are used wherever available.

4 These guidelines were selected based on analysis using the AGREE tool, which ensures that guidelines have been developed in a rigorous, transparent and robust manner. This process is discussed in detail in Appendix 2.

5 Due to a paucity of evidence or low quality evidence some systematic reviews were not used to draft recommendations.
Limitations of the grading process as it applies to the practice of infection control

The recommendations in these guidelines were formulated by the Infection Control Steering Committee through a process of consensus. Recommendations are given when an action is deemed critical to preventing or managing infection. Recommendations are graded according to the revised NHMRC gradings for assessing evidence, with the addition of good practice points, which outline actions that are essential to infection prevention and control but where evidence grades cannot be applied.

In many areas of infection prevention and control, the evidence may be limited by the inability to conduct certain study designs that are difficult to implement in real practice. This has implications for the level of grading that is assigned to the recommendations, since grading systems will tend to favour study designs that are sometimes not feasible or ethical to conduct in infection control settings, such as randomised controlled trials. For example, it is unethical to compare the incidence of infection related to surgical instruments by allocating one patient group to have sterilised instruments used on them and one patient group to have non-sterile instruments used on them. This may result in a lower grading due to the available evidence but sterilisation of surgical instruments is universally deemed critical to infection control.

Given that there is limited evidence available to support many routine practices intended to reduce infection risk, practice is based on decisions made on scientific principles. Some activities, such as performing hand hygiene between administering care to successive patients, have a credible history to support their routine application in preventing cross-infection. Others, such as some uniform and clothing requirements, have more to do with the ethos of quality care and workplace culture than with a proven reduction of cross-infection.

It is not acceptable to discontinue practices for which there is a solid scientific basis, even if the level of evidence is not high. Rather, routine practices should continue unless there is sufficient evidence to support alternative procedures. Continuing research is needed to keep evaluating practice, to identify evidence gaps and promote research in these areas, and to ensure that poor practices do not continue.

The ICG Steering Committee also assigned an additional ‘grade’ referred to as a good practice point (GPP).

| GPP  | Body of evidence is weak or non-existent. Recommendation for best practice based on clinical experience and expert opinion |
Structure of the guidelines

These guidelines are based around the following core principles:

• an understanding of the modes of transmission of infectious agents and of risk management
• effective work practices that minimise the risk of transmission of infectious agents
• governance structures that support the implementation, monitoring and reporting of infection prevention and control work practices
• compliance with legislation, regulations and standards relevant to infection control.

The parts of the document are based on these core principles and are organised according to the likely readership.

Part A presents background information that should be read by everyone working in healthcare (for example as orientation or as part of annual review)—this includes important basics of infection prevention and control, such as the main modes of transmission of infectious agents and the application of risk-management principles. This part of the guidelines does not include recommendations.

Part B is specific to the practice of healthcare workers and support staff, and outlines effective work practices that minimise the risk of transmission of infectious agents. Recommendations are given in Sections B1 to B3. Each section includes advice on putting the recommendations into practice, a risk-management case study and resources.

Section B1 describes standard precautions used at all times to minimise the risk of transmission of infectious agents

Section B2 outlines transmission-based precautions to guide staff in the presence of suspected or known infectious agents that represent an increased risk of transmission

Section B3 outlines approaches to the management of multi-resistant organisms (MROs) or outbreak situations

Section B4 outlines processes for risk identification and the application of standard and transmission-based precautions for certain procedures

Section B5 includes supplementary information to assist in the application of standard and transmission-based precautions.

Part C describes the responsibilities of management of healthcare facilities, including governance structures that support the implementation, monitoring and reporting of effective work practices. The chapters outline the main components of a systems approach to facility-wide infection prevention and control, giving guidance on management and staff responsibilities, protection of healthcare workers, requirements for education and training of all staff, considerations for facility design and renovation, and other important activities such as surveillance and antibiotic stewardship.

Legislation, regulations and standards relevant to infection prevention and control are listed at the end of each section before the references.

The appendices provide additional information on the guideline development process.
Key information is highlighted in the guidelines as follows.

**Table 4: Key to types of information highlighted in the guidelines**

PART A

BASICS OF INFECTION PREVENTION AND CONTROL

Summary

- Healthcare-associated infections (HAIs) can occur in any healthcare setting. While the specific risks may differ, the basic principles of infection prevention and control apply regardless of the setting.
- In order to prevent HAIs, it is important to understand how infections occur in healthcare settings and then institute ways to prevent them. Risk management is integral to this approach.
- If effectively implemented, the two-tiered approach of standard and transmission-based precautions recommended in these guidelines provides high-level protection to patients, healthcare workers and other people in healthcare settings.
- Infection prevention and control is integral to clinical care and the way in which it is provided. It is not an additional set of practices.
- Involving patients and their carers is essential to successful clinical care. This includes ensuring that patients’ rights are respected at all times, that patients and carers are involved in decision-making about care, and that they are sufficiently informed to be able to participate in reducing the risk of transmission of infectious agents.

The information presented in this part is relevant to everybody employed by a healthcare facility, including management, healthcare workers and support service staff.
A1.1 Risks of contracting a healthcare-associated infection

Most infectious agents are microorganisms. These exist naturally everywhere in the environment, and not all cause infection (e.g. ‘good’ bacteria present in the body’s normal flora). Several classes of microorganism—including bacteria, viruses, fungi, parasites and prions—can be involved in either colonisation or infection, depending on the susceptibility of the host:

- With colonisation, there is a sustained presence of replicating infectious agents on or in the body, without the production of an immune response or disease.
- With infection, invasion of infectious agents into the body results in an immune response, with or without symptomatic disease.

Transmission of infectious agents within a healthcare setting requires the following elements:

- a source or reservoir of infectious agents
- a mode of transmission
- a susceptible host.
Infectious agents transmitted during health care come primarily from human sources, including patients, healthcare workers and visitors. Source individuals may be actively ill, may have no symptoms but be in the incubation period of a disease, or may be temporary or chronic carriers of an infectious agent with or without symptoms. Other sources of transmission include:

- endogenous flora of patients (e.g. bacteria residing in the respiratory or gastrointestinal tract)
- environmental sources such as air, water, medications or medical equipment and devices that have become contaminated.

Infection is the result of a complex interrelationship between a host and an infectious agent and people vary in their response to exposure to an infectious agent:

- some people exposed to infectious agents never develop symptomatic disease while others become severely ill and may die
- some individuals may become temporarily or permanently colonised but remain asymptomatic
- others progress from colonisation to symptomatic disease either soon after exposure, or following a period of asymptomatic colonisation.

Important predictors of an individual’s outcome after exposure include his or her:

- immune status at the time of exposure (including whether immune status is compromised by medical treatment such as immunosuppressive agents or irradiation)
- age (e.g. neonates and elderly patients are more susceptible)
- health status (e.g. when a patient has other underlying disease such as diabetes or is a smoker);
- the virulence of the agent
- other factors that increase the risk of transmission of infection (e.g. undergoing surgery, requiring an indwelling device such as a catheter, or remaining in hospital for lengthy periods).
In healthcare settings, the most common susceptible hosts are patients and healthcare workers.

- Patients may be exposed to infectious agents from themselves (endogenous infection) or from other people, instruments and equipment, or the environment (exogenous infection). The level of risk relates to the healthcare setting (specifically, the presence or absence of infectious agents), the type of healthcare procedures performed and the susceptibility of the patient.

- Healthcare workers may be exposed to infectious agents from infected or colonised patients, instruments and equipment, or the environment. The level of risk relates to the type of clinical contact healthcare workers have with potentially infected or colonised patient groups, instruments or environments, and the health status of the healthcare worker (e.g. immunised or immunocompromised).

In healthcare settings, the main modes of transmission of infectious agents are contact (including bloodborne), droplet and airborne. The modes of transmission vary by type of organism. In some cases the same organism may be transmitted by more than one route (e.g. norovirus, influenza and respiratory syncytial virus [RSV] can be transmitted by contact and droplet routes).
A1.1.1 Routes of transmission

Contact transmission

Contact is the most common mode of transmission, and usually involves transmission by touch or via contact with blood or body substances. Contact may be direct or indirect.

- **Direct transmission** occurs when infectious agents are transferred from one person to another—for example, a patient's blood entering a healthcare worker's body through an unprotected cut in the skin.

- **Indirect transmission** involves the transfer of an infectious agent through a contaminated intermediate object or person—for example, a healthcare worker's hands transmitting infectious agents after touching an infected body site on one patient and not performing hand hygiene before touching another patient, or a healthcare worker coming into contact with fomites (e.g. bedding) or faeces and then with a patient.

Examples of infectious agents transmitted by contact include multi-resistant organisms (MROs), *Clostridium difficile*, norovirus and highly contagious skin infections/infestations (e.g. impetigo, scabies).

Droplet transmission

Droplet transmission can occur when an infected person coughs, sneezes or talks, and during certain procedures. Droplets are infectious particles larger than 5 microns in size.\(^6\) Respiratory droplets transmit infection when they travel directly from the respiratory tract of the infected person to susceptible mucosal surfaces (nasal, conjunctivae or oral) of another person, generally over short distances. Droplet distribution is limited by the force of expulsion and gravity and is usually at least 1 metre. However, droplets can also be transmitted indirectly to mucosal surfaces (e.g. via hands).

Examples of infectious agents that are transmitted via droplets include influenza virus and meningococcus.

Airborne transmission

Airborne dissemination may occur via particles containing infectious agents that remain infective over time and distance. Small-particle aerosols are created during breathing, talking, coughing or sneezing and secondarily by evaporation of larger droplets in conditions of low humidity. Certain procedures, particularly those that induce coughing, can promote airborne transmission. These include diagnostic sputum induction, bronchoscopy, airway suctioning, endotracheal intubation, positive pressure ventilation via face mask and high-frequency oscillatory ventilation. Aerosols containing infectious agents can be dispersed over long distances by air currents (e.g. ventilation or air conditioning systems) and inhaled by susceptible individuals who have not had any contact with the infectious person. These small particles can transmit infection into small airways of the respiratory tract.

Examples of infectious agents that are transmitted via the airborne route include measles (rubeola) virus, chickenpox (varicella) virus and *M. tuberculosis*.

Other modes of transmission

Transmission of infection can also occur via common sources such as contaminated food, water, medications, devices or equipment.

---

A1.2 Standard and transmission-based precautions

Successful infection prevention and control involves implementing work practices that prevent the transmission of infectious agents through a two-tiered approach including:

- routinely applying basic infection prevention and control strategies to minimise risk to both patients and healthcare workers, such as hand hygiene, personal protective equipment, cleaning and appropriate handling and disposal of sharps (standard precautions)
- effectively managing infectious agents where standard precautions may not be sufficient on their own—these specific interventions control infection by interrupting the mode of transmission (transmission-based precautions; formerly referred to as additional precautions).

If successfully implemented, standard and transmission-based precautions prevent any type of infectious agent from being transmitted.

A1.2.1 Standard precautions

All people potentially harbour infectious agents. Standard precautions refer to those work practices that are applied to everyone, regardless of their perceived or confirmed infectious status and ensure a basic level of infection prevention and control. Implementing standard precautions as a first-line approach to infection prevention and control in the healthcare environment minimises the risk of transmission of infectious agents from person to person, even in high-risk situations.

Standard precautions are used by healthcare workers to prevent or reduce the likelihood of transmission of infectious agents from one person or place to another, and to render and maintain objects and areas as free as possible from infectious agents. Guidance on implementing standard precautions is given in Sections B1 and B5.

### A1.2.2 Transmission-based precautions

Any infection prevention and control strategy should be based on the use of standard precautions as a minimum level of control. Transmission-based precautions are recommended as extra work practices in situations where standard precautions alone may be insufficient to prevent transmission. Transmission-based precautions are also used in the event of an outbreak (e.g. gastroenteritis), to assist in containing the outbreak and preventing further infection.

Transmission-based precautions should be tailored to the particular infectious agent involved and its mode of transmission. This may involve a combination of practices.

Guidance on when and how to implement transmission-based precautions is given in Sections B2, B3 and B5.

**Contact precautions** are used when there is known or suspected risk of direct or indirect contact transmission of infectious agents that are not effectively contained by standard precautions alone (see Section B2.2).

**Droplet precautions** are used for patients known or suspected to be infected with agents transmitted over short distances by large respiratory droplets (see Section B2.3).

**Airborne precautions** are used for patients known or suspected to be infected with agents transmitted person-to-person by the airborne route (see Section B2.4).
A2 Overview of risk management in infection prevention and control

Summary

- Identifying and analysing risks associated with health care is an integral part of successful infection prevention and control.
- Adopting a risk-management approach at all levels of the facility is necessary. This task requires the full support of the facility’s management as well as cooperation between management, healthcare workers and support staff.
- Differing types and levels of risk exist in different healthcare settings. In developing local policies and procedures, each healthcare facility should conduct its own risk assessment (i.e. how to avoid, identify, analyse, evaluate and treat risks in that setting), and also refer to discipline-specific guidance where relevant.

A2.1 Risk management basics

In the context of these guidelines, ‘risk’ is defined as the possibility of acquisition or infection of patients or healthcare workers arising from activities within a healthcare facility. Risk management is the basis for preventing and reducing harms arising from healthcare-associated infection. A successful approach to risk management occurs on many levels within a healthcare facility:

- **facility wide**—for example, providing support for effective risk management through an organisational risk-management policy, staff training, follow-up of outcomes and monitoring and reporting
- **ward or department based**—for example, embedding risk management into all policies so that risks are considered in every situation
- **individual**—for example, considering the risks involved in carrying out a specific procedure and questioning the necessity of the procedure as part of clinical decision-making, attending education sessions (e.g. hand hygiene or respirator fit testing).

As healthcare settings differ greatly in their day-to-day function, it is not possible to provide a one size fits all approach to risk management. Even within a single setting (e.g. primary care), increasingly complex care is delivered by a range of health professionals with diverse qualifications and training. All healthcare facilities need to be able to determine the risks in their own context and select the appropriate course of action. Therefore it is necessary for facilities to regularly conduct infection prevention risk assessments within their facility and ensure that all staff understand their responsibility in managing these risks.

The Australian/New Zealand Standard on Risk Management AS/NZS ISO 31000:2009 outlines a stepwise approach to risk management that allows continuous quality improvement and involves:

- **establishing context**—identifying the basic parameters in which risk must be managed (e.g. the type of health facility, the extent of and support for the facility’s infection prevention and control program)
- **avoiding risk**—establishing whether there is a risk and whether potential risk can be averted (e.g. by questioning whether a procedure is necessary)
- **identifying risks**—a systematic and comprehensive process that ensures that no potential risk is excluded from further analysis and treatment (e.g. using root cause analysis)
• **analysing risks**—considering the sources of risk, their consequences, the likelihood that those consequences may occur, and factors that affect consequences and likelihood (e.g. existing controls) (see risk analysis matrix below)

• **evaluating risks**—comparing the level of risk found during the analysis process with previously established risk criteria and assessing available options for ease of implementation and impact, resulting in a prioritised list of risks for further action

• **treating risks**—implementing appropriate management options for dealing with identified risk (e.g. modifying procedures, protocols or work practices; providing education; and monitoring compliance with infection prevention and control procedures).

<table>

<tr>
<td>Possible</td>
</tr>
<tr>
<td>Likely</td>
</tr>
<tr>
<td>Almost certain</td>
</tr>
</tbody>
</table>

| Low risk          | Manage by routine procedures. |
| Medium risk       | Manage by specific monitoring or audit procedures. |
| High risk         | This is serious and must be addressed immediately. |
| Very high risk    | The magnitude of the consequences of an event, should it occur, and the likelihood of that event occurring, are assessed in the context of the effectiveness of existing strategies and controls. |
| Extreme risk      |                                     |

Monitoring and review is an essential component of the risk-management process. This ensures that:

• new risks are identified

• analysis of risk is verified against real data, if possible

• risk treatment is implemented effectively.

Communication and consultation are also key elements of clinical risk management. An interactive exchange of information between management, healthcare workers, patients and other stakeholders provides the basis for increased awareness of the importance of infection prevention and control, identification of risks before they arise and prompt management of risks as they occur.
A2.2 Risk management process

The following flowchart outlines key considerations during the process of risk management in the context of infection prevention and control in the healthcare setting.

**Figure A2.1: Risk-management flowchart**

- **Avoid risk**
  - Are there alternative processes or procedures that would eliminate the risk?
  - If a risk cannot be eliminated then it must be managed

- **Identify risks**
  - What infectious agent is involved?
  - How is it transmitted?
  - Who is at risk (patient and/or healthcare worker)?

- **Treat risks**
  - What will be done to address risk?
  - Who takes responsibility?
  - How will change be monitored and reviewed?

- **Analyze risks**
  - Why can it happen (activities, processes)?
  - What are the likely consequences?
  - What is the risk rating? (see Table A2.1)

- **Evaluate risks**
  - What can be done to reduce or eliminate the risk?
  - How could this be applied in this situation (staff, resources)?

The following case study gives an example of applying the risk-management process in a primary care setting. Case studies giving examples of how to use this process in primary, acute and long-term care settings, including relevant considerations in specific situations, are included in Part B. While the basic process of risk management applies regardless of setting, all healthcare facilities should develop risk-management policies and procedures that are appropriate to the setting.
Case study: measles (rubeola) virus outbreak

State health authorities notify a general practice of an outbreak of measles, and will assist the practice with advice about management of potential exposures.

Communicate and consult
- Information about the outbreak is communicated to clinicians and practice staff.
- Collaboratively, protocols and procedures are formulated to implement at the practice if there is a presentation of measles (see below).
- Communication occurs between clinicians, managers and reception staff to ensure that all understand why protocols and procedures are in place and that there is a clear understanding of how to apply them.

Establish context
- In developing protocols and procedures, consideration is given to the following questions:
  - Are there members of the practice community likely not to be immunised against measles or at risk (e.g. young children, recent migrants)?
  - Is this an area where uptake of immunisation low due to issues of access or acceptance?
  - What aspects of the practice offer the opportunity for the transmission of measles infection?

Identify risks
- Consideration is given to how measles might be transmitted within the practice:
  - What can happen? This includes the range of activities undertaken at the facility and that are associated with the airborne transmission of measles.
  - Where and when? The primary risk is exposure of non-immune patients to infectious patients in the waiting room or contact with non-immune staff.
  - How and why? The infection can be transmitted to any susceptible person breathing the same air as an infectious patient for up to 2 hours after the patient has left the area.
  - Failure to ensure that all staff members are vaccinated/immune, and inadequate use of PPE by non-immune staff.

Analyse risks
- Facility staff members consider and discuss the consequences and likelihood of transmission of infection in their particular setting.
- Using the risk analysis matrix above, the risks associated with the measles outbreak are assessed as high, requiring immediate action.

Note that in other settings, outcomes of the analysis may reveal a lower level of risk (e.g. if there is sufficient herd immunity in the community to not pose a risk) or a higher level of risk (e.g. if there are insufficient resources to manage airborne precautions and triage of patients).

Evaluate risks
- Consideration given to which risks can be managed and which cannot be tolerated using an ease of impact analysis—this involves examining the measures that can be implemented and the ease of implementing and impact of each measure (see examples below).
- Priority is given to the activities that are the simplest to do and have the greatest impact but does not exclude activities that are hard to do if their impact is high.

Note that priority must be given to activities that address risks that are high and which have a potentially catastrophic outcome.
<table>
<thead>
<tr>
<th>Example</th>
<th>Ease</th>
<th>Analysis</th>
<th>Impact</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disinfect surfaces with spray</td>
<td>Easy</td>
<td>No more effective than detergent solution; surfaces not a high risk cause of measles transmission</td>
<td>Low</td>
</tr>
<tr>
<td>Provide ABHR in waiting, clinical rooms and consultation rooms</td>
<td>Easy</td>
<td>Shown to improve compliance with hand hygiene, which has an impact on the spread of HAI</td>
<td>Low</td>
</tr>
<tr>
<td>Change linen between each patient in consultation rooms</td>
<td>Hard</td>
<td>Linen not a high risk cause of measles transmission</td>
<td>Low</td>
</tr>
<tr>
<td>Educate infectious patients to report their infectious state prior to attending practice</td>
<td>Hard</td>
<td>May reduce the incidence of iatrogenic infection</td>
<td>High</td>
</tr>
</tbody>
</table>

**Treat risks**
- A sign is placed on the door advising patients who suspect they may have measles to phone before entering the practice, so that the doctor can see them in their home, or they can be put into a separate waiting area where they will not mix with other patients.
- Patient information is displayed at reception warning about suspected measles cases.
- Respiratory etiquette is encouraged and alcohol-based hand rub dispenser placed in waiting and consultation rooms (this is good practice but will not reduce transmission of measles).
- Additional education is provided for staff on measles identification and management.
- At-risk staff identified, vaccinated, and requested to wear a P2 respirator for which they have been fit-tested (see B2.4.3).
- Uptake of patient and staff immunisation against measles is encouraged; staff vaccination policy established.

**Monitor and review**
- Mechanisms are implemented to ensure early awareness of notifications from public health authorities to assist in the early implementation of additional infection control measures.

---

7 This action has a low impact in terms of measles because the virus is spread through airborne transmission. However, use of ABHR can have a high impact in reducing the spread of microorganisms transmitted via contact or droplet routes (e.g. norovirus, influenza).
A3  A patient-centred approach

Summary

- A patient-centred health system is known to be associated with safer and higher quality care.
- A two-way approach that encourages patient participation is essential to successful infection prevention and control.

A3.1  Patient-centred health care

People receiving healthcare increasingly expect to be given information about their condition and treatment options and this extends to their rights and responsibilities as users of healthcare services. Although patient satisfaction with health services in Australia is generally high, patients’ experiences are not always valued and their expectations are not always met. While this does not necessarily lead to poor outcomes for the individuals concerned, the best possible outcomes are more likely where patient-centred health care is a priority of the healthcare facility and a strong and consistent effort is made to respect patients’ rights and expectations.

The ACSQHC has developed an *Australian Charter of Healthcare Rights*, which recognises that people receiving care and people providing care all have important parts to play in achieving healthcare rights. The Charter allows patients, families, carers and services providing health care to share an understanding of the rights of people receiving health care. The Charter stipulates that all Australians have the right to:

- access services that address their healthcare needs
- receive safe and high quality health services, provided with professional care, skill and competence
- receive care that shows respect to them and their culture, beliefs, values and personal characteristics
- receive open, timely and appropriate communication about their health care in a way they can understand
- join in making decisions and choices about their care and about health service planning
- have their personal privacy and personal health and other information properly handled
- comment on or complain about their care and have their concerns dealt with properly and promptly.

Patient-centred care cannot just be ‘added on’ to usual care. The rights, experiences and views of patients should be at the centre of the care process and drive the way in which care is delivered. In most healthcare facilities, a significant culture change is necessary to embed patient-centred care principles into the philosophy and practices of the organisation. Healthcare workers and organisations need to acknowledge and understand the Charter of Healthcare Rights and work to ensure that patients’ rights are integral to the care process.

---

A3.2 How does patient-centred care relate to infection prevention and control?

Infection prevention and control is ultimately about people. Effective infection prevention and control is central to providing high quality, patient-centred health care.

Putting patients at the centre of infection prevention and control and enabling them to participate in the care process is not just about explaining the risks of treatments, but involves considering patients’ needs at every level. This ranges from designing the facility to maximise patient comfort and safety to having a range of processes to engage patients in their care and listen and act on their feedback as well as providing the patient with education and support so that they can be involved in looking after themselves.

To support a two-way approach to infection prevention and control and encourage the patient participation required to minimise cross-infection or transmission, it is important to:

• take patients’ perspectives into account when developing policies and programs
• familiarise patients with the infection prevention and control strategies that are employed in healthcare facilities to protect them, the people caring for them and the healthcare environment
• discuss with patients the specific risks associated with their medical and/or surgical treatment
• encourage patients to disclose their health or risk status if there is a potential risk or source of infection to healthcare workers or others within the healthcare facility
• provide opportunities for patients to identify and communicate risks and encourage them to use feedback procedures for any concerns that they have about infection prevention and control procedures
• provide educational materials about infection prevention and control using a variety of media (e.g. posters in waiting rooms, printed material and educational videos)
• inform patients about the protocols for protecting their privacy and confidentiality.

Specific guidance on providing patient-centred care is highlighted throughout the guidelines, in text boxes, in the ‘Putting it into practice’ section at the end of each chapter in Part B, and in each chapter of Part C.
PART B
STANDARD AND TRANSMISSION-BASED PRECAUTIONS

Summary

• The use of standard precautions is the primary strategy for minimising the transmission of healthcare-associated infections.
• Transmission-based precautions are used in addition to standard precautions, where the suspected or confirmed presence of infectious agents represents an increased risk of transmission.
• The application of transmission-based precautions is particularly important in containing multi-resistant organisms (MROs) and in outbreak management.
• Medical and dental procedures increase the risk of transmission of infectious agents. Effective work practices to minimise risk of transmission of infection related to procedures require consideration of the specific situation, as well as appropriate use of standard and transmission-based precautions.

The information presented in this part is particularly relevant to healthcare workers and support staff. It outlines effective work practices that minimise the risk of transmission of infectious agents.

Patient-care tip

In applying standard and transmission-based infection prevention and control strategies as part of day-to-day practice, healthcare workers should ensure that their patients understand why certain practices are being undertaken, and that these practices are in place to protect everyone from infection. Patients and visitors should also be aware of their role in minimising risks by following basic hand hygiene and respiratory hygiene and cough etiquette and informing staff about aspects of their care or services if necessary.
B1 Standard precautions

Summary

It is essential that standard precautions are applied at all times. This is because:

- people may be placed at risk of infection from others who carry infectious agents
- people may be infectious before signs or symptoms of disease are recognised or detected, or before laboratory tests are confirmed in time to contribute to care;
- people may be at risk from infectious agents present in the surrounding environment including environmental surfaces or from equipment
- there may be an increased risk of transmission associated with specific procedures and practices.

Standard precautions consist of:

- hand hygiene, before and after every episode of patient contact
- the use of personal protective equipment
- the safe use and disposal of sharps;
- routine environmental cleaning;
- reprocessing of reusable medical equipment and instruments
- respiratory hygiene and cough etiquette
- aseptic non-touch technique;
- waste management;
- appropriate handling of linen.

Standard precautions should be used in the handling of blood (including dried blood); all other body substances, secretions and excretions (excluding sweat), regardless of whether they contain visible blood; non-intact skin; and mucous membranes.

Evidence supporting practice

The majority of the recommendations in this section have been adapted from:

These guidelines were selected based on analysis using the AGREE tool, which ensures that guidelines have been developed in a rigorous, transparent and robust manner. This process is discussed in detail in Appendix 2.
Further review of the evidence elicited good quality evidence on the use of alcohol-based hand rubs in reducing transmission of infectious agents.

Maiwald (2009) Systematic review of the efficacy of alcohol preparations and other agents for hand hygiene in the healthcare setting. Project report to the National Health and Medical Research Council (NHMRC), Canberra ACT, Australia.

The following Australian guidelines were also consulted during the development of this section:

**B1.1 Hand hygiene**

**B1.1.1 What are the risks?**

Any infectious agent transmitted by the contact or droplet route can potentially be transmitted by touch.

Microorganisms are either present on the hands most of the time (resident flora) or acquired during activities such as healthcare (transient flora). Hands can also become contaminated through contact with respiratory secretions when coughing or sneezing. Contaminated hands can lead to cross-transmission of infectious agents in non-outbreak situations (Pratt et al 2001; Boyce & Pittet 2002; Pratt et al 2007) and contribute to outbreaks involving organisms such as methicillin-resistant Staphylococcus aureus (MRSA), vancomycin-resistant enterococci (VRE) and multi-resistant Gram-negative (MRGN) microorganisms, such as Acinetobacter spp (Pratt et al 2001).

![Figure B1.1: Importance of hand hygiene](image)

*These images illustrate the critical importance of hand hygiene in caring for patients, including those not known to carry antibiotic-resistant organisms. An imprint of a healthcare worker’s ungloved hand was obtained after routine abdominal examination of a patient with no history of MRSA infection but found on routine surveillance to have MRSA colonisation. The resultant culture shows MRSA colonies (image on left). Another hand imprint obtained after the worker’s hand had been cleaned with alcohol-based hand rub was negative for MRSA (image on right).*

Improved hand hygiene practices have been associated with:

- reductions in healthcare-associated infections of up to 45% in a range of healthcare settings (Fendler et al 2002; Pittet et al 2000; Ryan et al 2001)
- greater than 50% reduction in the rates of nosocomial disease associated with MRSA and other multi-resistant organisms, after 1–2 years (Grayson et al 2009; Johnson et al 2005).

Hand hygiene practices alone are not sufficient to prevent and control infection and need to be used as part of a multifactorial approach to infection control.

This section discusses routine hand hygiene. Surgical hand preparation is discussed in Section B4.3.2.

**B1.1.2 When should hand hygiene be performed?**

Hands can become contaminated with infectious agents through contact with a patient, patient surroundings, the environment, or other healthcare workers. Cross-contamination can occur from one site to another in the same patient, between healthcare worker and patient, between patient or healthcare worker and the environment, or between healthcare workers. Practicing hand hygiene before every episode of patient contact (including between caring for different patients and between different care activities for the same patient) and after any activity or contact that potentially results in hands becoming contaminated (such as removal of gloves) reduces the risk of cross-contamination.

**The 5 moments for hand hygiene**

The ‘5 moments for hand hygiene’ developed by the World Health Organization (WHO 2009) and adopted by Hand Hygiene Australia (Grayson et al 2009):

- protect patients against acquiring infectious agents from the hands of the healthcare worker
- help to protect patients from infectious agents (including their own) entering their bodies during procedures
- protect healthcare workers and the healthcare surroundings from acquiring patients’ infectious agents.
Hand hygiene is also performed after the removal of gloves.

While Figure B1.2 illustrates application of the 5 moments in an acute-care setting, the 5 moments are still generally applicable to other healthcare settings including primary care. The key emphasis in any setting is to perform hand hygiene before and after any procedure, and after each consultation with a patient.

Table B1.1

#### B1.1.3 What product should be used?

Existing guidelines (WHO 2009; Boyce & Pittet 2002; Pratt et al 2007; Canada Standards and Guideline Core Committee 2008; PIDAC 2008) and literature reviews (Pittet & Boyce 2001; Picheansathian 2004; Rotter 2004; Nicolay 2006; Larmer et al 2008; Grayson et al 2009) agree that hand hygiene using alcohol-based hand rubs is more effective against the majority of common infectious agents on hands than hand hygiene with plain or antiseptic soap and water.

One advantage of alcohol-based hand rubs is that they are easily accessible at point of care. They have (Grayson et al 2009):

- excellent antimicrobial activity against Gram-positive and Gram-negative vegetative bacteria, *Mycobacterium tuberculosis* and a wide range of fungi
- generally good antimicrobial activity against enveloped viruses
- lesser and/or variable antimicrobial activity against non-enveloped viruses (such as norovirus)
- no activity against protozoan oocysts and bacterial spores (such as *C. difficile*) (see Section B2.2).

The range of antimicrobial activity in alcohol-based hand rubs varies with the alcohol compound (ethanol, isopropanol or n-propanol) used. Different alcohol species have different levels of activity (60% v/v n-propanol is approximately equivalent to 70% v/v isopropanol and to 80% v/v ethanol) and many commercial formulations consist of blends of different alcohol species. Most published clinical studies that have demonstrated reductions in HAIs with the use of alcohol-based hand rubs have been associated with products that contain at least 70% alcohol (isopropanol), 0.5% chlorhexidine and a skin emollient (Grayson et al 2009). However the efficacy of alcohol-based hand hygiene products is affected by a number of factors including the type of alcohol used, concentration of alcohol, contact time, volume of product used, and whether the hands are wet when the product is applied. These factors are generally assessed through testing standards for skin disinfectants, for which TGA is the regulatory body responsible for approving products for use in Australia.
Plain soaps act by mechanical removal of microorganisms and have no antimicrobial activity. They are sufficient for general social contact and for cleansing of visibly soiled hands. They are also used for mechanical removal of certain organisms such as _C. difficile_ and norovirus.

When _C. difficile_ and non-enveloped viruses are suspected or known to be present, use of alcohol-based hand rubs alone may not be sufficient to reduce transmission of these organisms. Alcohol-based hand rubs are effective at removing vegetative forms of _C. difficile_, but not effective at removing spores (Maiwald 2009). If gloves are worn during the care of patients in settings where _C. difficile_ or non-enveloped viruses are suspected or known to be present, spore contamination of the hands will be minimal and alcohol-based hand rub remains the agent of choice for hand hygiene (Johnson et al 1990; Jabbar et al 2010). [41, 42] However, if gloves have not been worn or the hands are visibly soiled, they must be meticulously washed with soap and water and patted dry, to facilitate the mechanical removal of spores.

There is a tendency for antimicrobial soaps to be more effective than plain soaps, although the evidence around this is inconsistent. Antimicrobial soap is associated with skin care issues and it is not necessary for use in everyday clinical practice (Pratt et al 2001; Boyce & Pittet 2002; Pratt et al 2007.)

Neutral hand-wipe products may be considered in instances where hygienic access to soap and water is not readily available, such as in community care settings. Alcohol-based hand rubs are also suitable for use in resource-limited or remote areas with lack of accessibility to sinks or other facilities for hand hygiene (including clean water, towels etc.).

**Choosing an alcohol-based handrub**

It is necessary to choose products:

- that have excellent antimicrobial efficacy combined with good user acceptability and skin tolerability (dermal tolerance, fragrance, colour, texture and ease of use)
- that are TGA approved for skin antisepsis
- meet the requirements of EN1500 testing standard for bactericidal effect (which are currently referred to by TGA).

Healthcare worker acceptance of alcohol-based hand rub is a crucial factor in the success of any program to improve hand hygiene practice. Several studies showed that user acceptability and skin tolerability tend to be determined by the overall hand rub composition (e.g. consistency as gel or rub, texture, fragrance) and by emollient additives, but both are largely independent of a formulation’s antimicrobial activity (Rotter et al 1991; Kramer et al 2002a; Girard et al 2006; WHO 2009). Even where emollient agents are present in the product, ready access to a moisturising skin-care product is essential (see Section B1.1.5). The selected alcohol-based hand rubs, soaps and moisturising lotions should be chemically compatible, to minimise skin reactions and ensure that the decontaminating properties of the hand hygiene product are not deactivated. It is advisable to purchase hand hygiene and hand-care products from a range made by a single manufacturer, as this ensures compatibility between the products.

Different healthcare workers and healthcare settings have different preferences, and the choice between a gel or liquid needs to be evaluated on an individual basis (Maiwald & Widmer 2007; Pittet 2007). In some healthcare facilities, it may be useful to offer both liquid and gel alongside each other, in order to provide a choice that suits a wide range of healthcare workers (Pittet 2007; Traore et al 2007, Girard R et al 2006). Some studies have noted that gel formulations have generally significantly less antimicrobial activity than liquid alcohol-based hand rub formulations, even if the total alcohol content is similar (Pietsch 2001; Kramer et al 2002b; Picheansathian 2004).
The *Hand Hygiene Australia Manual* (Grayson et al 2009) outlines the following alcohol-based hand rub features as important in influencing acceptability, as well as ready accessibility at each bedside and in all patient-care areas:

- **fragrance and colour**—these may increase the initial appeal but may cause allergenic reactions, and are therefore discouraged
- **emollient agent(s) in the alcohol-based hand rub**—these should prevent skin drying and irritant skin reactions, but not leave a sticky residue on hands
- **drying characteristics**—in general, solutions have lower viscosity than gels and therefore tend to dry more quickly
- **risk of skin irritation and dryness**—proactive and sympathetic management of this problem is vital.

There is some evidence to suggest that gels are preferred to solutions (WHO 2009), however it is important for staff to evaluate products themselves before implementation where possible. Even where emollient agents are present in the product, ready access to a moisturising skin-care product is essential. All hand hygiene products should be chemically compatible. It is advisable that hand hygiene and hand-care products are from a range made by a single manufacturer, as this ensures compatibility between the products.

**Other issues associated with alcohol-based hand rubs**

Other factors that should be considered when choosing products include cost issues, availability, convenience and functioning of dispenser, and ability to prevent contamination. Consideration should also be given to occupational health and safety issues associated with alcohol-based hand rubs. Alcohols are flammable, and healthcare workers handling alcohol-based preparations should respect safety standards. Accidental and intentional ingestion and dermal absorption of alcohol-based products used for hand hygiene have also been reported (Roberts et al 2005; Brown et al 2007). The risk of these issues can be mitigated by appropriate placement of dispensers within the facility (see Section C; in addition, the Hand Hygiene Australia risk assessment form outlines the safety issues in more detail).

<tr>
<td>Hand hygiene should be performed using soap and water when <em>Clostridium difficile</em> or non-enveloped viruses such as norovirus are known or suspected to be present and gloves have not been worn. After washing, hands should be dried thoroughly with single-use towels.</td>
</tr>
</tbody>
</table>

**Technique**

Effective hand hygiene relies on appropriate technique as much as on selection of the correct product. Inappropriate technique can lead to failure of hand hygiene measures to appropriately remove or kill microorganisms on hands, despite the superficial appearance of having complied with hand hygiene requirements.
Key factors in effective hand hygiene and maintaining skin integrity include (Boyce & Pittet 2002):
- the duration of hand hygiene measures
- the exposure of all surfaces of hands and wrists to the preparation used (Widmer & Dangel 2004)
- the use of rubbing to create friction
- ensuring that hands are completely dry.

Table B1.2: Use of alcohol-based hand rub

- Apply the amount of alcohol-based hand rub recommended by the manufacturer onto dry hands.
- Rub hands together so that the solution comes into contact with all surfaces of the hand, paying particular attention to the tips of the fingers, the thumbs and the areas between the fingers.
- Continue rubbing until the solution has evaporated and the hands are dry.

Table B1.3: Using soap (including antimicrobial soap) and water

- Wet hands under tepid running water and apply the recommended amount of liquid soap.
- Rub hands together for a minimum of 15 seconds so that the solution comes into contact with all surfaces of the hand, paying particular attention to the tips of the fingers, the thumbs and the areas between the fingers.
- Rinse hands thoroughly under running water, then pat dry with single-use towels.

B1.1.4 Other aspects of hand hygiene

As intact skin is a natural defence against infection, cuts and abrasions reduce the effectiveness of hand hygiene practices. Breaks or lesions of the skin are possible sources of entry for infectious agents (Larson 1996) and may also be a source of them. Similarly, the presence of fingernail disease may reduce the efficacy of hand hygiene and result in the transmission of pathogens (WHO 2009). To reduce the risk of cross-transmission of infectious agents, cuts and abrasions should be covered with waterproof dressings.

The type and length of fingernails can have an impact on the effectiveness of hand hygiene (Boyce & Pittet 2002; Lin et al 2003). Artificial or false nails have been associated with higher levels of infectious agents, especially Gram-negative bacilli and yeasts, than natural nails (Pottinger et al 1989; Passaro et al 1997; Foca et al 2000; Hedderwick et al 2000; Moolenaar et al 2000; Parry et al 2001; Boyce & Pittet 2002; Gupta et al 2004; Boszczowski et al 2005). Fingernails should therefore be kept short (e.g. the length of the finger pad) and clean, and artificial fingernails should not be worn. Studies have also demonstrated that chipped nail polish may support the growth of organisms on the fingernails (Grayson et al 2009). It is good practice to not wear nail polish, but if it must be used it should not be chipped and should be removed every 4 days (AORN 2007).

Although there is less evidence concerning the impact of jewellery on the effectiveness of hand hygiene, rings can interfere with the technique used to perform hand hygiene resulting in higher total bacterial counts (Boyce & Pittet 2002). Hand contamination with infectious agents is increased with ring wearing (Boyce & Pittet 2002; Trick et al 2003), although no studies have related this practice to healthcare worker-to-patient transmission. The consensus recommendation is to strongly discourage the wearing of watches, rings or other jewellery during health care; however if jewellery must be worn in clinical areas it should be limited to a plain band (e.g. wedding ring) and this should be moved about on the finger during hand hygiene practices. In high-risk settings such as operating suites/rooms, any jewellery, even a plain band, should not be worn.

Each healthcare facility should develop policies on the wearing of jewellery, artificial fingernails or nail polish by healthcare workers.
B1.1.5 Hand care

The main type of skin irritation associated with hand hygiene, irritant contact dermatitis, includes symptoms such as dryness, irritation, itching and sometimes cracking and bleeding. Allergic contact dermatitis is rare and represents an allergy, which may be to some ingredient in a hand hygiene product.

Generally, alcohol-based hand rubs cause significantly less skin reaction or irritation than hand hygiene with plain or antiseptic soaps (Pittet & Boyce 2001).

Expert opinion concludes that (Pratt et al 2001; Boyce & Pittet 2002; Grayson et al 2009):

- skin damage is generally associated with the detergent base of the preparation, poor hand hygiene technique and/or frequent use of alcohol-based hand rub immediately before or after performing hand hygiene with soap
- frequent use of hand hygiene agents may cause damage to the skin and alter normal hand flora
- excoriated hands are associated with increased colonisation by potentially infectious agents
- the irritant and drying effects of hand preparations are one reason why healthcare workers fail to adhere to hand hygiene guidelines
- appropriate use of hand lotion or moisturisers added to hand hygiene preparations is an important factor in maintaining skin integrity, encouraging adherence to hand hygiene practices and assuring the health and safety of healthcare workers.

Use of hand cream

An emollient hand cream should be applied regularly, such as after performing hand hygiene before a break or going off duty, and when off duty. Hand hygiene technique should be reviewed if skin irritation occurs. If the irritation persists or if it caused by a particular soap, antiseptic agent or alcohol-based product, the person with designated responsibility for infection control or occupational health should be consulted.

B1.1.6 Putting it into practice

Individual actions for reducing the risk

- Follow the 5 moments for hand hygiene, even when it seems that there is not enough time
- Become familiar with your facility policy on hand hygiene and follow it
- Use the appropriate product for the situation and use it as directed
- Follow facility policy on cuts and abrasions, fingernails, nail polish and jewellery
- Use hand-care products provided by your organisation; your own products may not be compatible with the hand hygiene products provided
- Minimise physical contact with patient surroundings
- Lead by example and champion hand hygiene in your setting
- Attend hand hygiene education sessions regularly to refresh your knowledge and skills
- Contact the person with designated responsibility for occupational health or infection prevention and control if you have a reaction to hand hygiene and hand-care products used in your setting
- If alcohol-based hand rub is not readily accessible at key points of care in a patient-care area, consider approaching management
Involving patients in hand hygiene

The following information may be provided to patients to assist them in becoming involved in identifying and reducing risks related to poor hand hygiene.

- Hand hygiene is the most important aspect of reducing the risk of infection—this applies to everyone including healthcare workers, patients and visitors.
- The ‘5 moments for hand hygiene’ tell healthcare workers, patients and visitors when hand hygiene should be performed to reduce the risk of infection.
- Healthcare workers generally use alcohol-based hand rub as it is effective and easy to use but, if their hands are visibly dirty, they need to use soap and water first.
- Performing hand hygiene regularly reduces the risk of infection to you and others. If in hospital, remind your visitors to use alcohol-based hand rub when they come into the ward and before they leave.
- No matter what product you use to clean your hands, the solution should come into contact with all surfaces.
- After hand hygiene, the hands should be dry. If alcohol-based hand rub is used, the solution will dry on the hands. After hand hygiene with soap and water, hands should be patted dry.
- Healthcare workers should have short, clean fingernails and not wear artificial fingernails or jewellery.
- It’s okay to question healthcare workers about their hand hygiene practices.

Risk-management case study

Hand hygiene in a neonatal intensive care unit

The neonatal intensive care unit in a large regional hospital identifies colonisation or infection with *Pseudomonas aeruginosa* in a number of infants. Surveillance cultures from other infants in the unit, from the hands of staff on the unit and from possible environmental reservoirs are assessed. The cultures show that an additional three infants are colonised. Cultures of environmental specimens are negative but cultures of three of twenty-four healthcare workers are positive. Of these, two have recently joined the unit and received no education on hand hygiene in orientation and the third has artificial fingernails.

<table>
<thead>
<tr>
<th>Eliminating risks</th>
<th>In this situation, it is not possible to eliminate risk, so it must be managed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifying risks</td>
<td>In this case, the risk has been identified as cross-transmission of <em>Pseudomonas aeruginosa</em>. Ongoing surveillance would assist in identifying other infectious agents that may be present in the neonatal intensive care unit.</td>
</tr>
<tr>
<td>Analysing risks</td>
<td>One source of the risk is the lack of appropriate hand hygiene practices by some staff members. Each time these staff members are involved in the care of an infected or colonised infant, there is potential for spread of the infectious agent (to other infants and to staff members), with the risk continuing until appropriate hand hygiene practices are performed. There is no mention in the case study of existing controls to counter the risk (e.g. use of gloves) but these would need to be included in the analysis, as would other possible causes of the risk (e.g. line setup, type of hand hygiene products available, reprocessing of equipment).</td>
</tr>
<tr>
<td>Evaluating risks</td>
<td>The balance of likelihood and consequences identify this as a ‘very high risk’ situation requiring immediate response including daily observations by clinical managers.</td>
</tr>
<tr>
<td>Treating risks</td>
<td>Immediate measures may include providing alcohol-based hand rub by each incubator, introducing clustering of patient-care activities to reduce contact, providing staff education sessions. In the longer term, improvements could be made to facility orientation processes. Banning the use of artificial fingernails in the unit might also be considered.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Hand hygiene compliance could be audited through direct observation by trained observers.</td>
</tr>

B1.2 Personal protective equipment

B1.2.1 What are the risks?

Any infectious agent transmitted by the contact or droplet route can potentially be transmitted by contamination of healthcare workers’ hands, skin or clothing. Cross-contamination can then occur between the healthcare worker and other patients or healthcare workers, or between the healthcare worker and the environment. Infectious agents transmitted through droplets can also come into contact with the mucous membranes of the healthcare worker.

Personal protective equipment (PPE) refers to a variety of barriers, used alone or in combination, to protect mucous membranes, airways, skin and clothing from contact with infectious agents. PPE used as part of standard precautions includes aprons, gowns, gloves, surgical masks, protective eyewear and face shields. Selection of PPE is based on the type of patient interaction, known or possible infectious agents, and/or the likely mode(s) of transmission.

There have been few controlled clinical studies evaluating the relationship between the use of PPE and risk of HAIs. However, the use of barriers reduces opportunities for transmission of infectious agents (Pratt et al 2001; Clark et al 2002). PPE also protects patients from exposure to infectious agents in the surrounding environment carried by healthcare workers.

This section discusses the routine use of PPE as part of standard precautions. Specific PPE used when transmission-based precautions are applied is discussed in Section B2. The use of PPE during specific procedures is discussed in Section B4.

B1.2.2 Decision-making about personal protective equipment

Selection of protective equipment must be based on assessment of the risk of transmission of infectious agents to the patient or carer, and the risk of contamination of the clothing or skin of healthcare workers or other staff by patients’ blood, body substances, secretions or excretions. Local policies and current health and safety legislation should also be taken into account (Clark et al 2002).

Factors to be considered are:

• probability of exposure to blood and body substances
• type of body substance involved
• probable type and probable route of transmission of infectious agents.

Appropriate sequences and procedures for putting on and removing PPE10 are shown in Section B1.2.7. Relevant Australian Standards are listed in B1.2.9.

All PPE must meet relevant Therapeutic Goods Administration (TGA) criteria for listing on the Australian Register of Therapeutic Goods (ARTG) or equivalent and should be used in accordance with manufacturer’s recommendations.

---

10 While it is acknowledged that ‘donning’ and ‘doffing’ are accepted terms for putting on and removing PPE, in these guidelines plain English terms are used for simplicity and clarity.
Where to wear PPE

PPE is designed and issued for a particular purpose in a protected environment and should not be worn outside that area. Protective clothing provided for staff in areas where there is high risk of contamination (e.g. operating suite/room) must be removed before leaving the area. Even where there is a lower risk of contamination, clothing that has been in contact with patients should not be worn outside the patient-care area. Inappropriate wearing of PPE (e.g. wearing operating suite/room attire in the public areas of a hospital or wearing such attire outside the facility) may also lead to a public perception of poor practice within the facility.

B1.2.3 Aprons and gowns

International guidelines recommend that protective clothing (apron or gown) be worn by all healthcare workers when (Garner 1996; Pratt et al 2001; Clark et al 2002; Pratt et al 2007):

• close contact with the patient, materials or equipment may lead to contamination of skin, uniforms or other clothing with infectious agents
• there is a risk of contamination with blood, body substances, secretions or excretions (except sweat).

The type of apron or gown required depends on the degree of risk, including the anticipated degree of contact with infectious material and the potential for blood and body substances to penetrate through to clothes or skin:

• a clean non-sterile apron or gown is generally adequate to protect skin and prevent soiling of clothing during procedures and/or patient-care activities that are likely to generate splashing or sprays of blood or body substances
• a fluid-resistant apron or gown should be worn when there is a risk that clothing may become contaminated with blood, body substances, secretions or excretions (except sweat).

Gowns and aprons must be changed between patients.

Clinical and laboratory coats or jackets worn over personal clothing for comfort and/or purposes of identity are not considered to be PPE. These items of clothing need to be changed dependant on activity and the extent of exposure to potential pathogens.

*Aprons/gowns are routinely used upon entering the room of a patient requiring contact precautions. This is discussed in Section B2.2.3.*

Plastic aprons

Single-use plastic aprons are recommended for general use when there is the possibility of sprays or spills, to protect clothes that cannot be taken off (Garner 1996; Pratt et al 2001; Clark et al 2002; Pratt et al 2007). Unused aprons should be stored in an appropriate area away from potential contamination (Callaghan 1998).

Gowns

Gowns are used to protect the healthcare worker's exposed body areas and prevent contamination of clothing with blood, body substances, and other potentially infectious material (Boyce et al 1994; Boyce et al 1995; Hall 2000; Kohn et al 2004).
Considerations in choosing a type of gown (e.g. long or short-sleeved) that is appropriate for the activity are:

- The volume of body substances likely to be encountered
- The extent and type of exposure to blood and body substances
- The probable type and route of transmission of infectious agents.

If a fluid-resistant full body gown is required, it is always worn in combination with gloves, and with other PPE when indicated. Full coverage of the arms and body front, from neck to the mid-thigh or below, ensures that clothing and exposed upper body areas are protected.

* Some gown types can be re-used. Reusable gowns need to be laundered or reprocessed according to AS/NZS4146—2000 Laundry Practice

### Removing aprons and gowns

Removal of aprons and gowns before leaving the patient-care area (e.g. in the room or anteroom) prevents possible contamination of the environment outside the patient’s room. Aprons and gowns should be removed in a manner that prevents contamination of clothing or skin. The outer, ‘contaminated’, side of the gown is turned inward and rolled into a bundle, and then discarded into a designated container for waste or linen to contain contamination (see Section B1.2.7).
5 Wearing of aprons/gowns

Aprons or gowns should be appropriate to the task being undertaken. They should be worn for a single procedure or episode of patient care and removed in the area where the episode of care takes place.

B1.2.4 Face and eye protection

The mucous membranes of the mouth, nose and eyes are portals of entry for infectious agents, as are other skin surfaces if skin integrity is compromised (e.g. by acne, dermatitis) (Sartori et al 1993; Rosen 1997; Keijman et al 2001; Hosoglu et al 2003).

Face and eye protection reduces the risk of exposure of healthcare workers to splashes or sprays of blood and body substances (Dancer 1999; Pratt et al 2001; Clark et al 2002) and is an important part of standard precautions. Procedures that generate splashes or sprays of blood, body substances, secretions or excretions require either a face shield or a mask worn with protective eyewear (CDC 1978; Davidson et al 1995; Gehanno et al 1999; Scales et al 2003; Seto et al 2003; Fowler et al 2004; Loeb et al 2004; ADA 2008).

Face and eye protection is worn as part of transmission-based precautions as discussed in Sections B2.2.3, B2.3.3 and B2.4.3.

Table B1.5: Use of face and eye protection as part of standard precautions

<td>Protective eyewear P2 respirator</td>
</tr>
</tbody>
</table>

Surgical masks

Surgical masks are loose fitting, single-use items that cover the nose and mouth. They are used as part of standard precautions to keep splashes or sprays from reaching the mouth and nose of the person wearing them. They also provide some protection from respiratory secretions and are worn when caring for patients on droplet precautions. Surgical masks differ from P2 respirators, as outlined in Table B1.6.
### Table B1.6: Properties of different types of mask

• Filtration through mechanical impaction  
• Fluid resistant | • Raised dome or duckbill  
• 4–5 layers (outer polypropylene, central layers electret [charged polypropylene])  
• Filtration through mechanical impaction and electrostatic capture |
| Sealing             | • Ties at crown and bottom of head                                           | • Ties at crown and bottom of head, pliable metal nose bridge  
• Fit testing and fit checking required (see B2.4.3) |
| Australian standards| • AS4381:2002                                                               | • AS1715:2009                                                                                   |
| Intended use        | • Procedures that generate splashes or sprays of large droplets of blood, body substances, secretions and excretions  
• Procedures requiring a surgical aseptic technique (to protect patients from exposure to infectious agents carried in a healthcare worker’s mouth or nose)  
• Routine care of patients on droplet precautions | • Routine care of patients on airborne precautions  
• High-risk procedures such as bronchoscopy when the patient’s infectious status is unknown  
• Procedures that involve aerosolisation of particles that may contain specific known pathogens |
| Notes               | • Care must be taken when placing respirators on patients and must suit clinical need (i.e. if the patient has chronic obstructive airways disease [COAD] or is in respiratory distress, the respirator will exacerbate symptoms) |

Surgical masks can be placed on coughing patients to limit potential dissemination of infectious respiratory secretions from the patient to others (see Section B2.3.3).

Considerations when using a surgical mask include:
- masks should be changed when they become soiled or wet
- masks should never be reapplied after they have been removed
- masks should not be left dangling around the neck
- touching the front of the mask while wearing it should be avoided
- hand hygiene should be performed upon touching or discarding a used mask.

Children should wear a specifically designed child mask and their oxygen saturation should be monitored.

**Eye protection**

Goggles with a manufacturer’s anti-fog coating provide reliable, practical eye protection from splashes, sprays, and respiratory droplets from multiple angles. Newer styles of goggles fit adequately over prescription glasses with minimal gaps (to be efficacious, goggles must fit snugly, particularly from the corners of the eye across the brow).
Other types of protective eyewear include safety glasses with side-shield protection, which are widely used in dentistry and other specialties that use operating microscopes (ADA 2008).

While effective as eye protection, goggles and safety glasses do not provide splash or spray protection to other parts of the face.

Personal eyeglasses and contact lenses are not considered adequate eye protection.

**Face shields**

Single-use or reusable face shields may be used in addition to surgical masks, as an alternative to protective eyewear. Compared with other forms of protective eyewear, a face shield can provide protection to other parts of the face as well as the eyes. Face shields extending from chin to crown provide better face and eye protection from splashes and sprays; face shields that wrap around the sides may reduce splashes around the edge of the shield.

**Removing face and eye protection**

Removal of a face shield, protective eyewear and surgical mask can be performed safely after gloves have been removed and hand hygiene performed. The ties, earpieces and/or headband used to secure the equipment to the head are considered ‘clean’ and therefore safe to touch with bare hands. The front of a mask, protective eyewear or face shield is considered contaminated.

**Cleaning reusable face and eye protection**

Reusable face shields and protective eyewear should be cleaned according to the manufacturer’s instructions, generally with detergent solution, and be completely dry before being stored. If they are to be disinfected, they should be disinfected using either a TGA-registered instrument grade disinfectant - low level, or by heat as per AS/NZS 4187:2003.

### B1.2.5 Gloves

Gloves can protect both patients and healthcare workers from exposure to infectious agents that may be carried on hands (Duckro et al 2005). As part of standard precautions, they are used to prevent contamination of healthcare workers’ hands when (Siegel et al 2007):

- anticipating direct contact with blood or body substances, mucous membranes, non-intact skin and other potentially infectious material

- handling or touching visibly or potentially contaminated patient-care equipment and environmental surfaces (Boyce & Pittet 2002; Bhalla et al 2004; Duckro et al 2005).

The capacity of gloves to protect healthcare workers from transmission of bloodborne infectious agents following a needlestick or other puncture that penetrates the glove barrier has not been determined (Siegel et al 2007).

*Gloves are an essential component of contact precautions (in particular for patients with MROs) (see Sections B2.2.3 and B3.1.2) and may also be used as part of droplet precautions (see Section B2.3.3).*
When and how should gloves be worn?

As with all PPE, the need for gloves is based on careful assessment of the task to be carried out, the related risk of transmission of microorganisms to the patient; and the risk of contamination of the healthcare worker's clothing and skin by the patient's blood and body substances (Pratt et al 2001; Clark et al 2002). Risk assessment includes consideration of:

- who is at risk (whether it is the patient or the healthcare worker)
- whether sterile or non-sterile gloves are required, based on contact with susceptible sites or clinical devices and the aspect of care or treatment to be undertaken
- the potential for exposure to blood or body substances
- whether there will be contact with non-intact skin or mucous membranes during general care and invasive procedures
- whether contaminated instruments will be handled.

When gloves are worn in combination with other PPE, they are put on last (see Section B1.2.7).

When should gloves be changed?

International guidance suggests that changing of gloves is necessary:

- between episodes of care for different patients, to prevent transmission of infectious material (Pratt et al 2001; Siegel et al 2007)
- during the care of a single patient, to prevent cross-contamination of body sites (CDC 1995; Boyce & Pittet 2002)
- if the patient interaction involves touching portable computer keyboards or other mobile equipment that is transported from room to room (Siegel et al 2007).

Prolonged and indiscriminate use of gloves should be avoided as it may cause adverse reactions and skin sensitivity (Pratt et al 2001; Clark et al 2002).

Hand hygiene should be performed before putting on gloves and after removal of gloves. Single-use gloves should not be washed, but discarded.

### Recommendations

<table>
<thead>
<tr>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>7 Wearing of gloves</strong></td>
</tr>
<tr>
<td>Gloves must be worn as a single-use item for:</td>
</tr>
<tr>
<td>• each invasive procedure;</td>
</tr>
<tr>
<td>• contact with sterile sites and non-intact skin or mucous membranes; and</td>
</tr>
<tr>
<td>• activity that has been assessed as carrying a risk of exposure to blood, body substances, secretions and excretions.</td>
</tr>
<tr>
<td>Gloves must be changed between patients and after every episode of individual patient care.</td>
</tr>
<tr>
<td><strong>8 Sterile gloves</strong></td>
</tr>
<tr>
<td>Sterile gloves must be used for aseptic procedures and contact with sterile sites.</td>
</tr>
</tbody>
</table>

What type of gloves should be worn?

Non-sterile single-use medical gloves are available in a variety of materials, the most common being natural rubber latex (NRL) and synthetic materials (e.g. nitrile). NRL remains the material of choice due to its efficacy in protecting against bloodborne viruses and properties that enable the wearer to maintain dexterity (Pratt et al 2001; Clark et al 2002). However, sensitivity to NRL in patients, carers and healthcare workers may occur (see below) and must be documented. A local policy is required on using alternative glove types when patients have latex allergies.
The selection of glove type for non-surgical use is based on a number of factors (Korniewicz et al 1994; Bolyard et al 1998; Korniewicz & McLeskey 1998; Ranta & Ownby 2004):

- the task to be performed (i.e. glove type should be fit for purpose and aim to avoid interference with dexterity, friction, excessive sweating or finger and hand muscle fatigue);
- anticipated contact with chemicals and chemotherapeutic agents; and
- personal factors, such as latex sensitivity and size.

Facility policies for creating a latex-free environment should also be taken into account.

**Latex allergy**

Latex allergy is a reaction to certain proteins in latex rubber. The amount of latex exposure needed to produce sensitisation or an allergic reaction is unknown. However, current understanding of latex allergy is as follows (NIOSH 1998):

- increasing the exposure to latex proteins increases the risk of developing allergic symptoms—most people who are allergic to latex have had frequent exposure to latex over many years; the majority are nurses, doctors, dentists or patients who have had a number of operations
- in sensitised people, symptoms usually begin within minutes of exposure; but they can occur hours later and can be quite varied—mild reactions involve skin redness, rash, hives, or itching; more severe reactions may involve respiratory symptoms such as runny nose, sneezing, itchy eyes, scratchy throat, and asthma (difficult breathing, coughing spells, and wheezing); and rarely, shock may occur although a life-threatening reaction is seldom the first sign of latex allergy
- the risk of latex allergy is influenced by the amount of protein/allergen and powder in the latex glove; not by powder alone (Hunt et al 2002).

Healthcare workers with latex allergies should inform their managers to ensure that their work areas can be latex free.

If latex gloves are used, they should be non-powdered due to the risks associated with aerosolisation and an increased risk of latex allergies.

**Removing and disposing of gloves**

Gloves (other than utility gloves) should be treated as single-use items. They should be put on immediately before a procedure and removed as soon as the procedure is completed.

When removing gloves, care should be taken not to contaminate the hands. After gloves have been removed, hand hygiene should be performed in case infectious agents have penetrated through unrecognised tears or have contaminated the hands during glove removal (Olsen et al 1993; Tenorio et al 2001; Boyce & Pittet 2002).

Gloves must not be washed for subsequent re-use—infected agents cannot be removed reliably from glove surfaces and continued glove integrity cannot be ensured. Glove re-use has been associated with transmission of methicillin-resistant *Staphylococcus aureus* (MRSA) and Gram-negative bacilli (Doebbeling et al 1988; Maki et al 1990; Olsen et al 1993).

Gloves should be disposed of as soon as they are removed, with disposal complying with local policies and standards.

**B1.2.6 Other items of clothing**

**Ties and lanyards**

There is some evidence to suggest that lanyards and neckties may play a role in transmission of infection but it is difficult to demonstrate the precise role (Kotsanas et al 2008).

**Footwear**

Footwear suitable for the duties being undertaken must be worn and preferably be designed to minimise the risk of injury from dropped sharps.

**Uniforms**

In areas of clinical practice where there is a high risk of repeated exposure to blood and other body substances, it is recommended that uniforms be worn as well as the appropriate PPE.
While some studies show that uniforms and white coats become progressively contaminated during clinical care, no studies have demonstrated that uniforms transmit infectious agents or lead to HAIs (Loveday et al 2007).

Uniforms should be washed daily. There is no evidence to suggest that home laundering is inferior to commercial reprocessing of uniforms (Loveday et al 2007).

### B1.2.7 Sequence for putting on and removing PPE

To reduce the risk of transmission of infectious agents, PPE must be used appropriately. The following table outlines sequences and procedures for putting on and removing PPE.

**Table B1.8: Putting on and removing PPE**

<table>
<thead>
<tr>
<th>SEQUENCE FOR PUTTING ON PPE</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>GOWN</strong></td>
</tr>
<tr>
<td>• Fully cover torso from neck to knees, arms to end of wrists, and wrap around the back</td>
</tr>
<tr>
<td>• Fasten at the back of neck and waist</td>
</tr>
<tr>
<td><strong>MASK</strong></td>
</tr>
<tr>
<td>• Secure ties or elastic bands at middle of head and neck</td>
</tr>
<tr>
<td><strong>PROTECTIVE EYEWEAR OR FACE SHIELD</strong></td>
</tr>
<tr>
<td>• Place over face and eyes and adjust to fit</td>
</tr>
<tr>
<td><strong>GLOVES</strong></td>
</tr>
<tr>
<td>• Extend to cover wrist of isolation gown</td>
</tr>
</tbody>
</table>
### SEQUENCE FOR REMOVING PPE

**GLOVES**
- Outside of gloves is contaminated!
- Grasp outside of glove with opposite gloved hand; peel off
- Hold removed glove in gloved hand
- Slide fingers of ungloved hand under remaining glove at wrist
- Peel glove off over first glove
- Discard gloves in waste container

**PERFORM HAND HYGIENE**

**PROTECTIVE EYEWEAR OR FACE SHIELD**
- Outside of eye protection or face shield is contaminated!
- To remove, handle by head band or ear pieces
- Place in designated receptacle for reprocessing or in waste container

**GOWN**
- Gown front and sleeves are contaminated!
- Unfasten ties
- Pull away from neck and shoulders, touching inside of gown only
- Turn gown inside out
- Fold or roll into a bundle and discard

**MASK**
- Front of mask is contaminated—DO NOT TOUCH!
- Grasp bottom, then top ties or elastics and remove
- Discard in waste container

**PERFORM HAND HYGIENE IMMEDIATELY AFTER REMOVING ALL PPE**

* Surgical masks can be removed at the point of care. To remove a P2 respirator, perform hand hygiene and step outside the room or into an anteroom before removing and disposing of the respirator in a closed container and performing hand hygiene again.

Note that for surgical procedures and dentistry, the sequence for putting on PPE differs. In these situations, masks and protective eyewear are applied first prior to hand preparation. Gown and gloves are then put on. (see Section B4.3.2).
B1.2.8 Putting it into practice

Individual actions for reducing the risk

- Before putting on PPE explain to the patient that it is a routine part of infection prevention and control
- Assess the risk of spraying or splashing in the specific situation and choose PPE accordingly
- If you have a sensitivity or allergy to latex, inform your manager and ensure you always use an alternative glove type
- Follow appropriate sequence and procedure for putting on and removing PPE outlined in table 1.8
- Remove PPE before leaving the patient-care area and follow the sequence and procedure outlined in table 1.8
- Lead by example and champion the appropriate use of PPE in your setting

Involving patients in their care

The following information may be provided to patients to assist them in becoming involved in identifying and reducing risks related to the use of PPE.

- The wearing of PPE such as gowns, masks and gloves is a routine part of infection prevention and control in healthcare—it is used for everybody’s safety
- The use of PPE alone is not enough—heathcare workers should perform hand hygiene before putting on and after removing the protective items
- PPE is used in the patient care area only—heathcare workers remove the equipment before they leave the area to reduce the risk of spreading infection
- Gowns or aprons are used so that the healthcare worker’s clothing or skin does not become contaminated
- Healthcare workers wear a mask if there is risk of them inhaling an infectious agent
- Masks, eye protection or faceshields are worn by a healthcare worker in situations where the patient’s body substances may splash onto his or her face
- Healthcare workers wear gloves when they will have direct hand contact with blood or body substances, mucous membranes or wounds or if there is a chance that touching the patient could transmit infection.
- Patients who are sensitive or allergic to latex should tell their healthcare workers so that an alternative glove type can be used
- It’s okay to question a healthcare worker about whether they should be using protective personal equipment or whether they are using it properly

Risk-management case study

Glove use and hand hygiene in office-based practice

Following an audit of healthcare-associated infections in the practice and comparison of the results with Division benchmarks, a GP identifies a higher than usual rate of Staphylococcus aureus cross-transmission in her practice. The practice comprises three GPs and a part-time practice nurse. Practice policy is that staff members use gloves for patient contact, changing gloves between patients. There is no recommendation in the policy for hand hygiene between different care activities for the same patient or after removing gloves.
Eliminating risks

As patients may present with Staphylococcus aureus infections or asymptomatic colonisation, in this situation it is not possible to eliminate risk, so it must be managed.

Identifying risks

The risk has been identified as cross-transmission of Staphylococcus aureus, with higher than usual rates occurring. Audit of cases of other infections that may be transmitted in the healthcare environment would assist in identifying other infectious agents that may occur at high rates in the practice.

Analysing risks

One source of the risk has been identified as the lack of hand hygiene before and after use of gloves. Each time a patient carrying Staphylococcus aureus is examined, there is potential for the spread of the infectious agent from the glove to the healthcare worker’s hand and then to the gloves worn for subsequent patients. The same applies for other infectious agents spread by contact.

Existing controls and other sources of risk (e.g. low availability of alcohol-based hand rub) would also need investigation.

Evaluating risks

The balance of likelihood and consequences identify this as a ‘very high risk’ situation requiring immediate response.

Treating risks

Immediate measures may include provision of alcohol-based hand rub at all points of care and staff education in hand hygiene and PPE. Long-term measures would include revision and implementation of PPE and hand hygiene policies. This could be carried out by the GP as practice leader, in consultation with other staff.

Monitoring

Changes in practice could be monitored through audit of amounts of gloves and alcohol-based hand rub used. Repeating the audit of patient infections at regular intervals would assist in monitoring improvements.

B1.3 Handling and disposing of sharps

B1.3.1 What are the risks?

The use of sharp devices exposes healthcare workers to the risk of injury and potential exposure to bloodborne infectious agents, including hepatitis B virus, hepatitis C virus and human immunodeficiency virus (HIV) (CDC 2001; Do et al 2003).

Sharps injuries can occur in any healthcare setting, including non-hospital settings such as in office-based practices, home health care and long-term care facilities. Injuries most often occur (CDC 2008):

- during use of a sharp device on a patient (41%);
- after use and before disposal of a sharp device (40%); and
- during or after appropriate or inappropriate disposal of sharp devices (15%).

There are many possible mechanisms of injury during each of these periods.

Hollowbore needles are of particular concern, especially those used for blood collection or intravascular catheter insertion, as they are likely to contain residual blood and are associated with an increased risk for bloodborne virus transmission. Non-hollowbore sharps such as glass vials and butterfly needles have also been involved in sharps incidents (ASCC 2008).

<table>
<thead>
<tr>
<th>Examples of hollowbore sharps</th>

</tr>
</tbody>
</table>

A survey of occupational exposures in Australian nurses (ASCC 2008) found that in the 12 months prior to the survey, 11.2% of nurses had sustained at least one needlestick or other sharps injury. Eliminating workplace hazard and risk is a fundamental principle of all occupational health and safety (OH&S) legislation in Australia. To limit the risk of sharps injuries, the hierarchy of controls method is a well recognised approach to prevent sharps injuries (CDC 2008; NOHSC 2010 [2003]). The first priority is to eliminate and reduce the use of needles and other sharps where possible. Next is to isolate the hazard, thereby protecting an otherwise exposed sharp, through the use of an engineering control. When these strategies are not available or will not provide total protection, the focus shifts to work-practice controls and PPE. An organisational approach to reducing sharps injuries is discussed in Section C1.5.2 and sharps injuries and post-exposure prophylaxis (PEP) in Section C6.3.
**B1.3.2 Handling of sharps**

All healthcare workers should take precautions to prevent injuries caused by needles, scalpels and other sharp instruments or devices: during procedures; when cleaning used instruments; during disposal of used needles; and when handling sharp instruments after procedures.

Standard measures to avoid sharps injuries include handling sharp devices in a way that prevents injury to the user and to others who may encounter the device during or after a procedure. Examples include (CDC 2008):

- using instruments, rather than fingers, to grasp needles, retract tissue, and load/unload needles and scalpels
- giving verbal announcements when passing sharps
- avoiding hand-to-hand passage of sharp instruments by using a basin or neutral zone
- using round-tipped scalpel blades instead of pointed sharp-tipped blades.

The extent to which gloves protect healthcare workers from transmission of bloodborne infectious agents following a needlestick or other puncture that penetrates the glove has not been determined (Siegel et al 2007). Although gloves may reduce the volume of blood on the external surface of a sharp (Mast et al 1993), the residual blood in the lumen of a hollowbore needle would not be affected; therefore, the effect on reduction of transmission risk is not quantifiable (Siegel et al 2007).

**Recommendations**

<table>
<thead>
<tr>
<th>Safe handling of sharps</th>
<th>Grade</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sharps must not be passed directly from hand to hand and handling should be kept to a minimum. Needles must not be recapped, bent or broken after use.</td>
<td>D</td>
</tr>
</tbody>
</table>

**B1.3.3 Disposal of single-use sharps**

Any person who has used a disposable sharp instrument or equipment must be responsible for its safe management and immediate disposal after use.

After they are used, single-use syringes and needles, scalpel blades and other sharp items should be placed in an appropriate container. These containers should be clearly labelled, puncture and leak proof, and conform to AS4031 or AS/NZ 4261. The containers should be located at the point of use or, if this is not possible, as close as practical to the use area. Reusable sharps requiring transport to a reprocessing area must be placed in a puncture-resistant lidded container.

Sharps containers must be appropriately placed so that they are out of reach of children. They should also be placed in a secure position or mounted on the wall to prevent tipping.

There are numerous safety devices available that assist with safe removal and disposal of sharps (eg scalpel blade removers). Local protocol and procedures need to be developed to outline their appropriate use.
Table B1.10: Reducing risks if a sharps injury is sustained

- Seek care immediately if you sustain a sharps injury.
- If skin is penetrated, wash the affected area immediately with soap and water. Alcohol-based handrub can be used to clean the area if soap and water are not available.
- Do not squeeze the affected area.
- Report the incident immediately to your supervisor.
- Ask about follow-up care, including post-exposure prophylaxis, which is most effective if implemented soon after the incident.
- Complete an accident/incident report form, including the date and time of the exposure, how it happened, and name of the source individual (if known).
- If a sharps injury happens to you, you can be reassured that only a small proportion of accidental exposures result in infection. Taking immediate action will lower the risk even further.

Recommendation

10. Disposal of single-use sharps

| The person who has used the single-use sharp must be responsible for its immediate safe disposal. Used disposable sharps must be discarded into an approved sharps container at the point-of-use. These must not be filled above the mark that indicates the bin is three-quarters full. |

B1.3.4 Safety-engineered devices

A broad range of devices has been designed with built-in safety features that reduce the risk of injury involving a sharp. Examples include devices such as syringes with guards, sliding sheaths, shielded, blunting or retracting needles, blunt suture needles and surgical blades with protective covers.

The use of devices with safety-engineered protective features (e.g. safety or retractable devices) was mandated in the US in 2000 and is thought to have reduced the rate of incidence of needlestick injuries (Jagger et al 2008). Their use has recently been mandated in the UK and Europe, but not yet in Australia. Further research is required on their efficacy in reducing sharps injuries and their impact on patient safety.

Needleless devices

Needleless devices do not use needles for procedures such as the collection or withdrawal of body substances after initial venous or arterial access is established, or administering medication or fluids.

Since their adoption in healthcare facilities, needleless devices have contributed to a decrease in percutaneous injuries among healthcare workers (Jagger et al 2008). While it is difficult to assess the overall effect of needleless devices because of the wide variety of devices and systems that are in use, some studies have shown an increased risk of bloodstream infections (BSI) among patients (Rupp et al 2007; Salgado et al 2007).
Unfamiliarity with the use of these complex devices, together with inadequate disinfection procedures, may contribute to increased BSI rates. The CDC recommends that (O’Grady et al 2002):

- the needleless components are changed at least as frequently as the administration set
- caps are changed no more frequently than every 3 days or according to manufacturer’s recommendations
- all components of the system are compatible to minimise leaks and breaks
- contamination risk is minimised by wiping the access port with an appropriate antiseptic and accessing the port only with sterile devices.

Disinfection of needleless connectors with chlorhexidine/alcohol or povidone-iodine has been shown to significantly reduce external contamination (Casey et al 2003).

Retractable devices
The use of retractable safety devices on sharps has been associated with a significant reduction in needlestick injury in healthcare settings (Rogues et al 2004; Tuma & Sepkowitz 2006), although their direct impact is difficult to determine because their introduction is often accompanied by other interventions (e.g. training and education, overarching hospital policies and other technologies) that in isolation could also cause a reduction in needlestick injuries (Whitby et al 2008).

Retractable technology is only one example of the broad range of safety-engineered medical devices that have been designed and produced to assist in reducing the risk of occupational exposure to bloodborne pathogens in healthcare.

Implementation of safety-engineered devices must be accompanied by appropriate training and education for healthcare workers in the use of the new technology to achieve successful reduction in percutaneous injury rates (Tuma & Sepkowitz 2006).

B1.3.5 Putting it into practice

Individual actions for reducing the risk

- Explain to patients the risks to healthcare workers and others involved in the use and disposal of sharps and the measures taken to reduce these
- Become familiar with facility protocols on handling and disposal of sharps
- Use the appropriate product for the situation and use it as directed
- Avoid using needles where safe and effective alternatives are available
- Before using any sharp medical device such as needles or scalpels, always plan for their safe handling and immediate disposal at the point-of-use
- Make sure every used sharp medical device such as needles, scalpels etc are disposed of properly in puncture-resistant sharps containers located at the point-of-use
- Report any needlestick or sharps-related injuries promptly as relevant (e.g. to infection control or occupational health and safety professional, management, insurer) and ensure that you receive appropriate follow-up care
- Ensure that you are vaccinated against blood-borne viruses such as hepatitis B
- Participate in education sessions and professional development sessions on handling sharps, as well as those on new safety devices and how to use them
Involving patients in their care

The following information may be provided to patients to assist them in becoming involved in identifying and reducing risks related to the handling and disposal of sharps.

- Healthcare workers are at risk of injury and infection when using sharp equipment such as needles and scalpels.
- Healthcare workers take measures to handle sharp devices in a way that prevents injury to the user and to others who may encounter the device during or after a procedure.
- Special containers are used for the disposal of sharp devices.
- It’s okay to question a healthcare worker about the way in which they are handling or disposing of sharp devices.
- Patients will be educated before discharge from hospital about how to safely dispose of sharps used in the home so there is no risk of injury to community members.

Risk-management case study

Prevention of stick injury during surgery at a university hospital

As part of the revision of infection control policies at a university hospital, an analysis of the risk of percutaneous blood and body substance exposure during surgical procedures was undertaken. Separate analyses were conducted for different device types and for different members of the surgical team. Surgeons and first assistants were at highest risk for injury, suffering more than half of injuries in the operating room, followed by scrub nurses and technicians, anaesthetists and circulating nurses. Rates of stick injury increased with estimated blood loss and surgery duration. Suture needle injuries were the most common and mostly occurred during wound closure. A considerable number of injuries also occurred while passing sharp instruments hand to hand. As many as one-third of devices that caused injury came into contact with the patient after injury to the healthcare worker. However, only a small proportion of injuries to surgeons (0.5%) involved hollowbore vascular access needles, which are defined as ‘high risk’.

<table>
<thead>
<tr>
<th>Eliminating risks</th>
<th>Although the risk of injury varies for different healthcare team members, it is never zero and must be managed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifying risks</td>
<td>In this case, the risk has been identified as exposure of healthcare workers to blood and body substances (and potential infection) through suture needle injury. As a high proportion of devices causing injury came into contact with the patient after injury to the healthcare worker, there could also be a risk of transmission of bloodborne infection to the patient.</td>
</tr>
<tr>
<td>Analysing risks</td>
<td>The fundamental source of risk is the need to use sharps coupled with the potential for a patient to be a source of infection. The level of risk increases with duration of procedure and amount of blood lost. Other factors that may contribute to the risk are levels of staff training and experience, staffing levels, the existence of a hospital policy for safe use of sharps and compliance with the policy. Other factors that would need to be included in the analysis are existing controls to mitigate risk (e.g. double gloving) and other possible causes (e.g. poor surgical technique increasing blood loss and procedure duration).</td>
</tr>
<tr>
<td>Evaluating risks</td>
<td>The balance of likelihood and consequences identify this as a ‘very high risk’ situation requiring immediate response.</td>
</tr>
<tr>
<td>Treating risks</td>
<td>Immediate measures may include providing staff education, use of blunt suture needles and a neutral zone for passing surgical equipment, and double gloving during long surgery. In the longer term, reviewing local policy on the prevention of needlestick injury and raising awareness of measures to reduce injury among staff members might also be considered.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Changes in adverse events could be evaluated by repeating the analysis after implementation of changes.</td>
</tr>
</tbody>

B1.3.7 References

**Bl.4 Routine management of the physical environment**

**Bl.4.1 What are the risks?**

Infectious agents can be widely found in healthcare settings and there is a body of clinical evidence, derived from case reports and outbreak investigations, suggesting an association between poor environmental hygiene and the transmission of infectious agents in healthcare settings (Garner & Favero 1986; Dancer 1999). Transmission of infectious agents from the environment to patients may occur through direct contact with contaminated equipment, or indirectly, for example, in the acute-care setting, via hands that are in contact with contaminated equipment or the environment and then touch a patient (Dancer 2008).

Environmental surfaces can be safely decontaminated using less rigorous methods than those used on medical instruments and devices. The level of cleaning required depends on the objects involved and the risk of contamination—for example, surfaces that are likely to be contaminated with infectious agents (e.g. shared clinical equipment) require cleaning between patient uses,
which is more often than general surfaces and fittings. However, all surfaces require regular cleaning. Thorough cleaning of all surfaces is necessary after spills and between patient uses of a room or patient-care area, especially in acute-care settings.

Intensive care units and isolation areas require additional levels of cleaning, especially where there is a risk of MRO transmission (see Section B2.2).

**B1.4.2 Routine environmental cleaning**

General surfaces can be divided into two groups—those with minimal hand contact (e.g. floors and ceilings) and those with frequent skin contact (‘frequently touched’ or ‘high risk’ surfaces). The methods, thoroughness and frequency of cleaning and the products used are determined by risk analysis and reflected in healthcare facility policy. Frequently touched surfaces in patient-care areas should be cleaned using a detergent solution and more frequently than surfaces with minimal hand contact. Infection control professionals typically use a risk-assessment approach to identify frequently touched surfaces and then coordinate an appropriately thorough cleaning strategy and schedule with the housekeeping staff. When MROs are suspected or known to be present, routine cleaning is intensified and the use of a detergent solution is followed by the use of a disinfectant so that surfaces are cleaned twice (see Section B3.1.2).

**Cleaning schedules**

The recommendations outlined for cleaning should be justified by the risk of transmission of infection within a particular healthcare facility. All organisations should have a documented cleaning schedule that outlines clear responsibilities of staff, a roster of duties and the frequency of cleaning required and the products that should be used to clean specific areas. Organisations should also facilitate job or task-specific education and training by accredited bodies for general and special cleaning of the physical environment.

If cleaning is outsourced to cleaning service providers, all cleaning service delivery procedures should be documented, including details of how the cleaning service will be undertaken. The procedures must include the following (VCSUG 2009).

- **Minimum cleaning frequencies and methods**: cleaning service providers are required to provide cleaning services at whatever frequencies are deemed necessary in order to meet required standards. Section B5.1 provides a guide for minimum frequencies for cleaning within a healthcare facility providing acute care. It can be used as a guide for other settings.

- **Staffing**: including rosters for full-time, part-time and relief staffing members, as well as for management and supervisory positions.

- **Equipment**: including provision of consumable items (such as cleaning fluids and toilet paper) and facilities to be used to deliver each cleaning service.

- **Management of the cleaning service**: how the cleaning services will be managed and controlled at the service level, including specific details of the on-site management functions.

The risk of transmission of particular infections should be assessed and the cleaning schedule should be adjusted if a known infectious agent is present (e.g. an outbreak of *C. difficile* requires surfaces to be disinfected with sodium hypochlorite after cleaning with detergent [HPS 2008]).

**Cleaning**

Most hard surfaces can be adequately cleaned with warm water and detergent as per manufactures instructions. Allowing the cleaned surface to dry is an important aspect of cleaning.
Minimal touch surfaces

A detergent solution (diluted as per manufacturer's instructions) is adequate for cleaning general surfaces (e.g. floors, walls), as well as non-patient-care areas (e.g. administrative offices). Damp mopping is preferable to dry mopping for routine cleaning (Andersen et al 2009).

Walls and blinds in patient-care areas should be cleaned with detergent solution when they are visibly dusty or soiled. Window curtains should be regularly changed in addition to being cleaned when soiled or exposed to MROs. Sinks and washbasins should be cleaned with a detergent solution on a regular basis as set by facility policy.

Frequently touched surfaces

Surfaces that are in close proximity to the patient and frequently touched surfaces in the patient-care areas should be cleaned more frequently than minimal touch surfaces. Examples include doorknobs, bedrails, over-bed tables, light switches, tabletops and wall areas around the toilet in the patient's room.

Frequently touched surfaces can be cleaned with a detergent solution designed for general purpose cleaning. The exact choice of detergent will depend on the nature of the surface and the likely degree of contamination. Detergent-impregnated wipes may be used to clean single pieces of equipment and small surface areas. This method is not normally used for general ward cleaning and should not be considered a replacement for clean cloths and detergent solution.

### Recommendation

<table>
<thead>
<tr>
<th>Recommendation</th>

<tr>
<td>Clean frequently touched surfaces with detergent solution at least daily, and when visibly soiled and after every known contamination.</td>
<td></td>
</tr>
<tr>
<td>Clean general surfaces and fittings when visibly soiled and immediately after spillage.</td>
<td></td>
</tr>
</tbody>
</table>

Use of disinfectants

In acute-care settings where there is uncertainty about the nature of soiling on the surface (e.g. blood or body fluid contamination versus routine dust or dirt) or the presence of MROs (including *C. difficile*) or other infectious agents requiring transmission-based precautions (e.g. pulmonary tuberculosis) is known or suspected, surfaces should be physically cleaned with a detergent solution, followed or combined with a TGA-registered disinfectant with label claims specifying its effectiveness against specific infectious organisms. This process must involve either:

- a physical clean using detergent followed by a chemical disinfectant (2-step clean) i.e. clean with detergent, then clean with a disinfectant
- a physical clean using a detergent and chemical disinfectant (2-in-1 clean) i.e. a combined detergent/disinfectant wipe or solution could be used if this process involves mechanical/manual cleaning.
- Physical (mechanical or manual) cleaning is the most important step in cleaning. Sole reliance on a disinfectant without mechanical/manual cleaning is therefore not recommended.

In office-based practice and less acute patient-care areas (e.g. long-term care facilities), the risk of contamination, mode of transmission and risk to others should be used to determine whether disinfectants are required.

High-level disinfectants or liquid chemical sterilants are not appropriate for general cleaning; such use is counter to manufacturers' instructions for these hazardous chemicals. Instrument disinfectants should not be used for surface disinfection. Alcohol should not be used to disinfect large environmental surfaces, given the risk of additional hazards such as flammability.

Technologies in this area are evolving and new technologies may replace the need for cleaning chemicals and disinfectants. Some current examples include ultramicrofibre cloths (Moore & Griffin 2006; Rutala 2007; Bergen et al 2008; Wren 2008) and hydrogen peroxide mist (Shapey 2008). More research is needed in these areas to assess the scope of organisms removed or killed and the practical application of these technologies.

Shared clinical equipment

While shared clinical equipment comes into contact with intact skin only and is therefore unlikely to introduce infection, it can act as a vehicle by which infectious agents are transferred between patients (Microbiological Advisory Committee to the Department of Health 2006). Examples of possible contaminated surfaces on shared medical equipment include knobs or handles on haemodialysis machines, x-ray machines, instrument trolleys and dental units (Sehulster & Chinn 2005). Cleaning frequencies for specific shared clinical equipment is outlined in Section B5.1.

Surface barriers (e.g. clear plastic wrap, bags, sheets, tubing or other materials impervious to moisture) help prevent contamination of surfaces and equipment. Surface barriers on equipment (e.g. air water syringes, bedboards, computer keyboards) need to be placed carefully to ensure that they protect the surfaces underneath and should be changed or cleaned between patients. If surface barriers are unable to be used, cleaning clinical surfaces including equipment still applies.
Recommendation

12 Cleaning of shared clinical equipment

Clean touched surfaces of shared clinical equipment between patient uses, with detergent solution.
Exceptions to this should be justified by risk assessment.

13 Surface barriers

Use surface barriers to protect clinical surfaces (including equipment) that are:
- touched frequently with gloved hands during the delivery of patient care
- likely to become contaminated with blood or body substances
- difficult to clean.
Exceptions to this should be justified by risk assessment.

Cleaning implements and solutions

Part of the cleaning strategy is to minimise contamination of cleaning solutions and cleaning tools. Proper procedures for effective use of mops, cloths, and solutions should be followed:
- prepare cleaning solutions daily or as needed, and replace with fresh solution frequently according to facility policy
- clean mops and cloths after use and allow to dry before reuse, or use single-use mop heads and cloths.

</tr>
</tbody>
</table>

Carpet

Carpets in public areas and in general patient-care areas should be vacuumed daily with well-maintained equipment fitted with high efficiency particulate air (HEPA) filters to minimise dust dispersion (see also Section C6.2.3). After a spill has been removed as much as possible (see Section B1.4.3), the carpet should be cleaned using the hot water extraction method, which is recognised by AS/NZS 3733:1995 to minimise chemical and soil residue.

Carpets should undergo thorough cleaning on a regular basis as set by facility policy, using a method that minimises the production of aerosols, leaves little or no residue and is recommended by Australian Standards and manufacturer’s recommendations.

Checking, auditing and environmental sampling

Healthcare facilities use a variety of systems to ensure that cleaning standards are met. These include checklists, colour coding to reduce the chance of cross infection, cleaning manuals, model cleaning contracts, infection control guidance, and monitoring strategies. Some states and territories have cleaning standards that are applied to healthcare facilities regardless of whether cleaning services are contracted or performed in-house.
Auditing of cleaning is mostly done through visual checking; however, this does not recognise that microorganisms are invisible to the naked eye (Dancer 2008). Currently, more objective methods of assessing surface cleanliness and benchmarking (such as black-spot auditing and detection of bacterial load with ATPase) are being investigated.

Routine microbiological sampling of the environment to determine the effectiveness of cleaning has considerable limitations, including detection of specific classes of organisms (with exclusion of others), inconsistency and unpredictability of ‘patient shedding’ and other causes of environmental contamination, variation of effects of residual detergent/disinfectants, and variations in sampling techniques and testing. These limitations make interpreting the results very difficult (Button 2006; Mutters et al 2009; Rohr et al 2009) and routine environmental sampling is therefore not recommended. However, there may be a role for environmental sampling in the management of specific situations and as part of a holistic risk-management approach (e.g. an outbreak situation or unidentified cause of infections).

B1.4.3 Management of blood and body substance spills

Prompt removal of spots and spills of blood and body substance followed by cleaning and disinfection of the area contaminated is a sound infection control practice and meets occupational health and safety requirements (Sehulster & Chinn 2003).

Process of spills management

Strategies for decontaminating spills of blood and other body substances (e.g. vomit, urine) differ based on the setting in which they occur and the volume of the spill:

- in patient-care areas, healthcare workers can manage small spills by cleaning with detergent solution
- for spills containing large amounts of blood or other body substances, workers should contain and confine the spill by:
  - removing visible organic matter with absorbent material (e.g. disposable paper towels)
  - removing any broken glass or sharp material with forceps
  - soaking up excess liquid using an absorbent clumping agent (e.g. absorbent granules).

The B1.12 table demonstrates appropriate processes when managing spills. Appropriate PPE should be worn at all times.

If spillage has occurred on soft furnishings, a detergent solution can be used to clean the area thoroughly. Do not clean soft furnishings with a disinfectant such as sodium hypochlorite.

Soft furnishings can also be wet vacuumed. Following cleaning of soft furnishings, every effort must be made to air the room to allow drying of the furnishing before reuse.

Alcohol solutions should not be used to clean spillages (HPS 2006).
<table>
<thead>
<tr>
<th><strong>Table B1.12: Management of blood or body substance spills</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Spot cleaning</strong></td>
</tr>
<tr>
<td>• Select appropriate PPE</td>
</tr>
<tr>
<td>• Wipe up spot immediately with a damp cloth, tissue or paper towel</td>
</tr>
<tr>
<td>• Discard contaminated materials</td>
</tr>
<tr>
<td>• Perform hand hygiene</td>
</tr>
<tr>
<td><strong>Small spills (up to 10cm diameter)</strong></td>
</tr>
<tr>
<td>• Select appropriate PPE</td>
</tr>
<tr>
<td>• Wipe up spill immediately with absorbent material</td>
</tr>
<tr>
<td>• Place contaminated absorbent material into impervious container or plastic bag for disposal</td>
</tr>
<tr>
<td>• Clean the area with warm detergent solution, using disposable cloth or sponge</td>
</tr>
<tr>
<td>• Wipe the area with sodium hypochlorite and allow to dry</td>
</tr>
<tr>
<td>• Perform hand hygiene</td>
</tr>
<tr>
<td><strong>Large spills (greater than 10cm diameter)</strong></td>
</tr>
<tr>
<td>• Select appropriate PPE</td>
</tr>
<tr>
<td>• Cover area of the spill with an absorbent clumping agent and allow to absorb</td>
</tr>
<tr>
<td>• Use disposable scraper and pan to scoop up absorbent material and any unabsorbed blood or body substances</td>
</tr>
<tr>
<td>• Place all contaminated items into impervious container or plastic bag for disposal</td>
</tr>
<tr>
<td>• Discard contaminated materials</td>
</tr>
<tr>
<td>• Mop the area with detergent solution</td>
</tr>
<tr>
<td>• Wipe the area with sodium hypochlorite and allow to dry</td>
</tr>
<tr>
<td>• Perform hand hygiene</td>
</tr>
</tbody>
</table>

The use of sodium hypochlorite is not necessary for routinely managing spills but it may be used in specific circumstances. There is evidence supporting the use of sodium hypochlorite to inactivate various bloodborne and gastrointestinal viruses, and bacteria such as *C. difficile* (HPS 2008). The consideration to use sodium hypochlorite should be based on risk assessment of the environment, the spill, risk of transmission of disease, and the surface area and potential hazards with using the product.

If a disinfectant is required, particularly during the implementation of transmission-based precautions, a TGA-registered hospital grade disinfectant must be used. The disinfectant chosen should have label claims against the organism of concern.
Recommendation

14 Site decontamination after spills of blood or other potentially infectious materials

Spills of blood or other potentially infectious materials should be promptly cleaned as follows:

- **wear utility gloves and other PPE** appropriate to the task;
- **confine and contain** spill, clean visible matter with disposable absorbent material and discard the used cleaning materials in the appropriate waste container;
- **clean** the spill area with a cloth or paper towels using detergent solution.

Use of chemical disinfectants such as sodium hypochlorite should be based on assessment of risk of transmission of infectious agents from that spill.

**Spill kit**

A spill kit should be readily available in each clinical area and should include a scoop and scraper, single-use gloves, protective apron, surgical mask and eye protection, absorbent agent, clinical waste bags and ties, and detergent. All parts should be disposable to ensure that cross-contamination does not occur.

**Bl.4.4 Putting it into practice**

**Individual actions for reducing the risk**

- Make sure you are familiar with facility policies on routine cleaning
- Familiarise yourself with the cleaning frequencies outlined in Section B5.1 (see page 161).
- Report any concerns you have about hygiene
- Consider ways to involve patients in monitoring the cleanliness of the patient-care area (e.g. through comments books on the ward, or a short questionnaire to be filled in before discharge)

**Involving patients in their care**

Patients are an integral part of the risk-management process. Following are points of advice to assist patients in becoming involved in identifying and reducing risks related to routine hospital hygiene.

- All surfaces and equipment in the patient-care environment are regularly cleaned to prevent transmission of infection—equipment is cleaned immediately after use (i.e. between patients)
- Surfaces that are touched often (such as doorknobs, bedrails, over-bed tables, light switches) and floors are cleaned daily, while surfaces that are touched less often (such as ceilings) are cleaned less frequently
- Blood or other body substances (such as urine or vomit) increase the risk of transmission of infection so they are cleaned away promptly
- You should notify staff if you think something needs to be cleaned

**Risk-management case study**

**Spills management in a busy paediatric ward**

A visitor to the paediatric ward in a small regional hospital notices that the child in the next bed is vomiting and has diarrhoea. The ward is extremely busy and the two nurses on duty are fully occupied. The child’s mother has cleaned up any spills, but there are still traces of vomit on the bedside table. Later the visitor notices that equipment is being placed on this table. When there is a lull in activity in the ward, the visitor approaches one of the nurses and mentions what she has noticed. The nurse is grateful for the advice and the quiet period is used for more thorough cleaning of surfaces around the vomiting child. The nurse thanks the mother for her assistance and explains to her the importance of thorough cleaning and hand hygiene in the prevention of transmission of infection.
Eliminating risks
Ideally, this risk can be eliminated through immediate removal and cleaning of spills. However, in many situations it is more likely that the risk will be managed.

Identifying risks
The risk has been identified as potential cross-transmission of Norovirus through environmental contamination.

Analysing risks
One source of the risk has been identified as inadequate environmental cleaning by a visitor resulting in potential contamination of equipment placed on environmental surfaces (bedside table) or hands touching this surface. There is then potential for direct or indirect spread of infection to other patients, visitors and healthcare workers.
There are likely to be other infectious agents that could be transmitted in the same way (e.g. Rotavirus).

Evaluating risks
The balance of likelihood and consequences identify this as a ‘high risk’ situation requiring immediate response.

Treating risks
Immediate measures may include raising patient and visitor awareness of hygiene measures (including hand hygiene as well as environmental cleaning). This could be done through posters and/or discussion with patients and carers on admission. Longer-term measures could include revision and implementation of environmental cleaning policies and involvement of patients/visitors in this review.

Monitoring
Changes in practice could be monitored through observation of patient/visitor behaviour.

B1.5 Reprocessing of reusable instruments and equipment

This section gives core principles for reprocessing of reusable instruments and equipment in any healthcare setting. Healthcare facilities should develop local policies and procedures relevant to their setting and may also need to consult relevant Australian standards and discipline-specific guidelines for further advice on reprocessing requirements.

B1.5.1 What are the risks?

Any infectious agents introduced into the body can establish infection. In all healthcare settings, reusable instruments and equipment should be handled in a manner that will prevent patient, healthcare worker and environmental contact with potentially infectious material. Principles of reprocessing reusable instruments and equipment include (TGA 1998):

- all reusable medical devices and patient-care equipment used in the clinical environment should be reprocessed according to their intended use and manufacturer's advice
- only TGA-registered reusable medical devices should be used; before purchase, healthcare facilities should ensure that manufacturer's reprocessing instructions are provided and are able to be followed by the healthcare facility
- single-use medical devices should not be reprocessed
- if a healthcare facility takes a decision to reprocess single-use devices, the facility must be licensed by the TGA
- will be considered a manufacturer
- will be subject to audit for conformance.

B1.5.2 Assessing the degree of risk

Any instrument or piece of equipment that is to be reused requires reprocessing—cleaning, disinfection and/or sterilisation. The minimum level of reprocessing required for reusable instruments and equipment depends on the individual situation (i.e. the body site and the nature by which the instrument will be used).

The approach to disinfection and sterilisation of patient-care items and equipment devised by Spaulding over 30 years ago has been retained and refined and is still successfully used by infection control professionals and others when planning methods for disinfection or sterilisation (Rutala & Weber 2008). The system is based on instruments and items for patient care being categorised into critical, semi-critical and non-critical, according to the degree of risk for infection involved in use of the items.

<table>
<thead>
<tr>
<th>Table B1.13: Categories of items for patient care</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Critical</strong></td>
</tr>
<tr>
<td>These items confer a high risk for infection if they are contaminated with any microorganism and must be sterile at the time of use. This includes any objects that enter sterile tissue or the vascular system, because any microbial contamination could transmit disease.</td>
</tr>
<tr>
<td><strong>Semi-critical</strong></td>
</tr>
<tr>
<td>These items come into contact with mucous membranes or non-intact skin, and should be single use or sterilised after each use. If this is not possible, high-level disinfection is the minimum level of reprocessing that is acceptable.</td>
</tr>
<tr>
<td><strong>Non-critical</strong></td>
</tr>
<tr>
<td>These items come into contact with intact skin but not mucous membranes. Thorough cleaning is sufficient for most non-critical items after each individual use, although either intermediate or low-level disinfection may be appropriate in specific circumstances.</td>
</tr>
</tbody>
</table>

Computers and personal digital assistants (PDAs) used in patient care should be included in policies for cleaning non-critical items. Although keyboard covers and washable keyboards that can
be easily cleaned are in use, the infection control benefit of these items and optimal management are yet to be determined.

B1.5.3 Cleaning

Cleaning is the removal of foreign material (e.g. soil and organic material) from objects and is normally accomplished using detergent solution.

Cleaning to remove organic material must always precede high-level disinfection and sterilisation of critical and semi-critical instruments and devices as residual proteinaceous material reduces the effectiveness of the disinfection and sterilisation processes. If an item cannot be cleaned, it cannot be disinfected or sterilised.

Instruments should be cleaned as soon as practical after use (e.g. preferably at the point of use) before soiled materials become dried onto the instruments. Dried or baked materials on the instrument make the removal process more difficult and the disinfection or sterilisation process less effective or ineffective.

Instruments that can be disassembled must be disassembled before the cleaning and the disinfection/sterilisation process.

Methods of cleaning

Automated

Automated cleaners (ultrasonic cleaners and washer-disinfectors) reduce the handling of instruments and are recommended for cleaning basic instruments that can withstand the process.

- Ultrasonic cleaners work by subjecting instruments to high frequency, high-energy sound waves, thereby loosening and dislodging dirt.
- Washer-disinfectors use detergent solutions at high temperatures to wash instruments. When a washer-disinfector is used, care should be taken in loading instruments: hinged instruments should be opened fully to allow adequate contact with the detergent solution; stacking of instruments in washers should be avoided; and instruments should be disassembled as much as possible.

Manual

Cleaning is done manually for fragile or difficult-to-clean instruments and in areas without automatic units.

The two essential components of manual cleaning are:

- friction—rubbing/scrubbing the soiled area with a soft brush
- fluidics—use of fluids to remove soil and debris from internal channels after brushing and when the design does not allow passage of a brush through a channel.

Healthcare workers should wear appropriate PPE for the task—plastic apron, utility gloves and face protection (protective eyewear and mask or face shield). Care should be taken to prevent splashes to mucous membranes or penetration of the skin by sharp instruments.

Cleaning agents

The cleaning solution and style must be appropriate for each instrument and equipment. The manufacturer's instructions will guide the type of cleaning agent required. This is usually neutral pH or mildly alkaline as such solutions generally provide the best material compatibility profile and good soil removal and mildly acidic solutions may damage instruments.

Enzymes, usually proteases, are sometimes added to neutral pH solutions to assist in removing organic material such as blood and pus. Cleaning solutions can also contain lipases (enzymes
active on fats) and amylases (enzymes active on starches). Enzymatic cleaners are not disinfectants, and proteinaceous enzymes can be inactivated by germicides.

As with all chemicals, enzymes must be rinsed from the equipment or adverse reactions could result.

**Checking effectiveness of cleaning**

During the past few years, data have been published describing use of an artificial soil, protein, endotoxin, X-ray contrast medium, or blood, to verify manual or automated cleaning processes and adenosine triphosphate bioluminescence and microbiologic sampling to evaluate the effectiveness of environmental surface cleaning (Rutala & Weber 2008). However, these are not used routinely in most healthcare facilities.

Australian Standards (AS 2945:2002) outline specific test methods to check the effectiveness of cleaning to verify manual and automated processes. At a minimum, all instruments should be individually inspected (with magnification where possible) and be visibly clean.

**B1.5.4 Disinfection**

Disinfection is a process that inactivates non-spore-forming infectious agents, using either thermal (moist or dry heat) or chemical means. Items need to be cleaned before being disinfected.

Instruments should be removed from the disinfectant after reprocessing and stored dry. To preserve the surfaces of the instruments, dissimilar metals should be separated before cleaning.

- **Thermal disinfection** uses heat and water, at temperatures that destroy infectious agents and is appropriate for items that are heat and moisture resistant and do not require sterilisation. Thermal disinfection, is the simplest, most efficient and cost-effective method of disinfection. It can be achieved in an automated thermal washer-disinfector by choosing the appropriate cycle.

- **Chemical disinfection** can be achieved with a compatible TGA-registered instrument-grade disinfectant, used alone or together with an automated washer-disinfector. Chemical disinfectants include alcohols, chlorine and chlorine compounds, formaldehyde, hydrogen peroxide, phenolics and quaternary ammonium compounds. Commercial formulations based on these chemicals are considered unique products and must be registered with the TGA. In most instances, each product is designed for a specific purpose; therefore, users should read labels carefully to ensure the correct product is selected for the intended use and applied efficiently.

There are three levels of disinfection, depending on the intended use of the instruments.

Disinfection is not a sterilising process. Wherever possible, sterilise items to be used in semi-critical sites, or employ single-use items.

**B1.5.5 Sterilisation**

Sterilisation destroys all microorganisms on the surface of an instrument or device, to prevent disease transmission associated with the use of that item. While the use of inadequately sterilised critical items represents a high risk of transmitting infectious agents, documented transmission associated with an inadequately sterilised critical item is rare. This is probably due to the wide safety margin associated with the sterilisation processes used in healthcare facilities.

- Reprocessing of heat resistant items is recommended by steam sterilisation due to the safety margin, reliability, validity and lethality.

- Reprocessing heat and moisture-sensitive items requires use of a low-temperature sterilisation technology (e.g. ethylene oxide, hydrogen peroxide plasma, peracetic acid, aldehyde).

Sterilisation methods are designed to give a sterility assurance level (SAL) of at least $10^{-6}$, provided the sterilisation process is validated by the user. Records of sterilisation must also be kept to verify that an
appropriate reprocessing system is in place according to state and federal legislation. Details of the documentation required can be found in Australian Standards AS/NZS 4187 and AS/NZS 4815.

In this rapidly changing area, reprocessing standards should evolve to accommodate changes in equipment design and emerging technologies in sterilisation.

**B1.5.6 Storage and maintenance**

All items must be stored in a way that that maintains their level of reprocessing (e.g. sterile, high level disinfected). Dry, sterile, packaged instruments and equipment should be stored in a clean, dry environment and protected from sharp objects that may damage the packaging. This is essential for instruments and equipment that are sterile and intended for use on critical sites.

Equipment and instrument surfaces should be regularly examined for breaks in integrity that would impair either cleaning or disinfection/sterilisation. Equipment that no longer functions as intended or cannot be properly cleaned and disinfected or sterilised should be repaired or discarded.

**Table B1.14: General criteria for reprocessing and storage of equipment and instruments in healthcare settings**

<table>
<thead>
<tr>
<th>Level of risk</th>
<th>Process</th>
<th>Examples</th>
<th>Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Critical</td>
<td>• Clean thoroughly as soon as possible after using</td>
<td>• Invasive surgical and dental equipment e.g. surgical oral instruments, arthroscopes, laparoscopes, rigid and flexible bronchoscopes, heat stable scopes</td>

<td></td>
</tr>
<tr>
<td></td>
<td>• If the equipment will not tolerate steam use a high level chemical or thermal disinfectant</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Non-critical</td>
<td>• Clean as necessary with detergent solution</td>
<td>• Stethoscopes, sphygmomanometers, blood pressure cuffs, mercury thermometers, non-invasive ultrasound probes</td>
<td>Store in a clean dry place to prevent environmental contamination</td>
</tr>
<tr>
<td></td>
<td>• If decontamination necessary, disinfect with compatible low or intermediate level TGA-registered disinfectant after cleaning</td>
<td>• Commodes, intravenous pumps and ventilators</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Noninvasive ultrasound probes</td>
<td></td>
</tr>
</tbody>
</table>

**Notes:** Critical items, particularly endoscopes, must be sterilised between patient uses. An invasive procedure is defined as entry into tissues, cavities or organs or repair of traumatic injuries.

**Source:** Rutala & Weber (2008).
Further considerations
Steam sterilisation and the other methods listed above are not sufficient for reprocessing items potentially contaminated with certain types of infectious agents. This includes prions, such as cCJD, for which single-use items should be used wherever possible and subsequently destroyed by incineration.

B1.5.7 Putting it into practice

Individual actions for reducing risk
- Become familiar with standards and facility protocols on cleaning, disinfecting and sterilising
- Use the appropriate product for the situation and use it as directed
- Participate in education sessions and professional development sessions on reprocessing instruments and equipment, particularly when new sterilising or disinfecting equipment is introduced

Involving patients in their care
The following information may be provided to patients to assist them in becoming involved in identifying and reducing risks related to reprocessing of instruments and equipment.

- Many instruments and equipment in the hospital are reusable
- All reusable instruments and equipment are cleaned thoroughly and then either disinfected or sterilised before being used on the next patient
- The system for cleaning, disinfecting and sterilising instruments and equipment protects patients and healthcare workers from contact with potentially infectious material
- Any instrument that enters a part of the body (e.g. in surgery) is sterilised and completely free of all potentially harmful organisms
- Any instrument that goes inside the nose, mouth or other orifice, or touches broken skin, is either sterilised or disinfected to a high level
- Any equipment that touches the patient or is touched by the patient, is cleaned thoroughly and if necessary disinfected
- It’s okay to ask about the cleaning and sterilising practices in the hospital

Risk-management case study
Reprocessing of instruments in a dental practice
A patient attends a dental practice for a scaling and cleaning of his teeth. He has moderate periodontal disease with inflamed gingiva (gums). The dentist uses both an ultrasonic scaler (which creates aerosol) and very sharp hand scalers and curettes. Neither the dentist nor the assistant wears a mask. To protect the tongue and cheeks of the patient from being injured by the sharp instruments, a dental mirror is used to retract them. The mirror consists of a handle into which a mirror bead is screwed. The handle of the mirror has a corrugated surface so that it doesn’t slip. During this procedure the mirror gets covered in blood from the bleeding of the inflamed diseased gums.
Eliminating risks
Proper reprocessing of the instrument, operator and assistant care in the use of sharp instruments and protecting against possible aerosol exposure has the potential to eliminate the risk.

Identifying risks
There is a risk of exposure of other patients to bloodborne viruses if the mirror is not reprocessed properly (i.e. still has blood on it or if the mirror head was constantly loose during the procedure). There is also a risk of exposure of staff to aerosol infectious agents (influenza in particular) and a risk of staff exposure to bloodborne viruses through sharps injury (either during the treatment or during reprocessing).

Analysing risks
Sources of the risk are difficulties in reprocessing the mirror; the use of multiple sharp instruments in a bloody field and aerosolisation caused by the treatment.

Evaluating risks
The balance of likelihood and consequences identify this as a ‘medium risk’ situation requiring management by specific monitoring or audit procedures.

Treating risks
Immediate measures include making sure that mirror handles are clean before sterilisation, operator care in the use of sharp instruments, use of high volume evacuation to reduce aerosolisation caused by this treatment and wearing of masks by operator and assistant. Longer-term measures could include revising practice PPE and instrument cleaning and reprocessing policies.

Monitoring
Repeated checking of reprocessed instruments, audits of staff sharps injuries and monitoring of PPE use would assist in assessing of the level of risk on an ongoing basis.

B1.6 Respiratory hygiene and cough etiquette

Respiratory hygiene and cough etiquette should be applied as a standard infection control precaution at all times. Covering sneezes and coughs prevents infected persons from dispersing respiratory secretions into the air. Hands should be washed with soap and water after coughing, sneezing, using tissues, or after contact with respiratory secretions or objects contaminated by these secretions.

Table B1.15: Steps in respiratory hygiene and cough etiquette

<table>
<thead>
<tr>
<th>Anyone with signs and symptoms of a respiratory infection, regardless of the cause, should follow or be instructed to follow respiratory hygiene and cough etiquette as follows:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Cover the nose/mouth with disposable single-use tissues when coughing, sneezing, wiping and blowing noses</td>
</tr>
<tr>
<td>• Use tissues to contain respiratory secretions</td>
</tr>
<tr>
<td>• Dispose of tissues in the nearest waste receptacle or bin after use</td>
</tr>
<tr>
<td>• If no tissues are available, cough or sneeze into the inner elbow rather than the hand</td>
</tr>
<tr>
<td>• Practice hand hygiene after contact with respiratory secretions and contaminated objects/materials</td>
</tr>
<tr>
<td>• Keep contaminated hands away from the mucous membranes of the eyes and nose</td>
</tr>
</tbody>
</table>
Health care/social workers should also assist patients (e.g. elderly, children) who need assistance with containment of respiratory secretions. Those who are immobile will need a receptacle (e.g. plastic bag) readily at hand for the immediate disposal of used tissues and will need to be offered hand hygiene facilities.

*Respiratory hygiene and cough etiquette are particularly important for patients on droplet precautions (see Section B2.3).*

**B1.7 Aseptic technique**

Aseptic technique protects patients during invasive clinical procedures by employing infection control measures that minimise, as far as practicably possible, the presence of pathogenic microorganisms.

**B1.7.1 Aseptic non-touch technique (ANTT)**

ANTT is a framework for aseptic practice—the principles are intended for use in a range of settings from the operating theatre to the community. Since 1993, the ANTT project (www.antt.org.uk) has helped implement ANTT through clinical guidelines and a standard implementation process, into hundreds of hospitals and community health organisations in the UK and internationally. As a result, ANTT has become the first standardised method of aseptic technique to exist in multiple hospitals and community care organisations. Hospitals that have implemented ANTT robustly have reported significant improvements in practice that have helped reduce rates of healthcare-associated infection (Rowley & Clare 2009).

**Terminology**

Historically, the practice of protecting patients from contamination and infection during clinical procedures has generated an inaccurate and confusing paradigm based on the terminology of undefined sterile, aseptic and clean techniques.

The use of accurate terminology is important in order to promote clarity in practice.

**Sterile** *Free from microorganisms* (Weller 1997)

Due to the natural multitude of organisms in the atmosphere it is not possible to achieve a sterile technique in a typical healthcare setting. Near sterile techniques can only be achieved in controlled environments such as a laminar air flow cabinet or a specially equipped theatre. The commonly used term, ‘sterile technique’ i.e. the instruction to maintain sterility of equipment exposed to air, is obviously not possible and is often applied inaccurately.
Asepsis ‘Freedom from infection or infectious (pathogenic) material’ (Weller 1997)

An aseptic technique aims to prevent pathogenic organisms, in sufficient quantity to cause infection, from being introduced to susceptible sites by hands, surfaces and equipment. Therefore, unlike sterile techniques, aseptic techniques are possible and can be achieved in typical hospital and community settings.

Clean ‘Free from dirt, marks or stains’ (Mcleod 1991).

Although cleaning followed by drying of equipment and surfaces can be very effective it does not necessarily meet the quality standard of asepsis (Ayliffe 2000). However, the action of cleaning is an important component in helping render equipment and skin aseptic, especially when there are high levels of contamination that require removal or reduction. However, to be confident of achieving asepsis an application of a skin or hard surface disinfectant is required either during cleaning or afterwards.

Consequently, the aim of any aseptic technique including ANTT, is asepsis.

ANTT in practice

ANTT is a technique used to prevent contamination of key parts and key sites by microorganisms that could cause infection. In ANTT, asepsis is ensured by identifying and then protecting key parts and key sites by hand hygiene, non-touch technique, using new sterilised equipment and/or cleaning existing key parts to a standard that renders them aseptic prior to use (Rowley et al 2010).

Risk assessment

While the principles of ANTT remain constant for all clinical procedures, the level of practice will change depending upon a standard ANTT risk assessment. Taking into account the technical difficulty of the procedure and his or her own competence, the healthcare worker assesses whether procedures can be performed without touching key parts and key sites directly. Infective precautions are then selected to counter the risks identified. For example, if it were necessary to touch a key part directly, sterile gloves would be the gloves of choice. Otherwise non-sterile gloves would be used.

B1.7.2 Core infection control components of ANTT

Key part and key site identification and protection

Key parts must be identified and protected at all times. Aseptic key parts must only come into contact with other aseptic key parts and/or key sites.

Hand hygiene

Effective hand hygiene is an essential component of ANTT. In Standard ANTT, hand hygiene should be performed as outlined in Section B1.1. In Surgical ANTT, a surgical hand scrub is required (ICNA 2002) (see Section B4.3.2).

It is known that hand hygiene is not always correctly performed and that even correctly performed hand hygiene cannot always remove all pathogenic organisms. Therefore, a non-touch technique—identifying ‘key parts’ and not touching them directly or indirectly—is a vital component of achieving asepsis. In other words, the safest way to protect a key part is not to touch it, even when wearing sterile gloves, as even sterile gloves can become contaminated.

Glove use

Gloves are single-use items. In ANTT, if it is necessary to touch key parts or key sites directly, sterile gloves are used to minimise the risk of contamination. Otherwise, non-sterile gloves are typically the gloves of choice.
Aseptic fields

Even well cleaned hospitals can be said to be ‘dirty’—busy and dynamic environments resident with unusual antibiotic-resistant organisms. Consequently, aseptic fields are important in providing a controlled aseptic working space to help promote or ensure the integrity of asepsis during clinical procedures. It is also important that aseptic fields are fit for purpose. In ANTT, aseptic fields are increased in size and sterilised drapes added on the basis of procedure complexity; for example in IV therapy, ‘mobile’ aseptic fields such as plastic trays should be large enough and with high sides to provide an adequate working space to contain equipment, sharps and spillages.

ANTT employs two types of aseptic field that require different management depending on whether the primary purpose is to promote or ensure asepsis.

Critical aseptic fields; ensuring asepsis

Critical aseptic fields are used when key parts and/or key sites, usually due to their size or number, cannot easily be protected at all times with covers and caps, or handled at all times by a non-touch technique (such as in PICC line, urinary catheter insertion, complex wound care etc), or when particularly open and invasive procedures demand large aseptic working areas for long durations, as in the operating room. In such cases, the critical aseptic field demands to be managed as a key part (i.e. only equipment that has been sterilised can come into contact with it). Such a critical aseptic field demands the use of sterilised gloves and, often, full barrier precautions (Pratt et al 2007). Large main critical aseptic fields are used in Surgical ANTT and as a result, technique is more complicated.

A sub-type of a main critical aseptic field is the critical micro aseptic field. Traditional non-touch/clean techniques have protected key parts by syringe caps, sheathed needles, covers or packaging etc. This often-understated approach is given new emphasis in ANTT, because the inside of such caps and covers have been sterilised and thus provide an optimum all-encompassing aseptic field for key parts.

General aseptic fields; promoting asepsis

General aseptic fields are used in Standard ANTT when key parts can easily and optimally be protected by critical micro aseptic fields and a non-touch technique. The main general aseptic field does not have to be managed as a key part and is essentially promoting rather than ensuring asepsis. Subsequently, aseptic technique is considerably simplified and typically involves non-sterile gloves.

Figure B1.4: Use of standard and surgical aseptic non-touch technique
Environmental control

Prior to aseptic procedures, healthcare workers must ensure that there are no avoidable nearby environmental risk factors, such as bed making or patients using commodes.

Sequencing

ANTT practice is sequenced to ensure an efficient, logical and safe order of procedure events. Section B5.4 provides examples of how to perform ANTT for peripheral and central access intravenous therapy and for wound care.

B1.7.3 Surgical or Standard ANTT?

Differentiation between Standard and Surgical ANTT is intended to provide clarity and structure to aid understanding, but not polarise practice. ANTT guidelines help standardise practice, technique and equipment levels.

- **Standard ANTT**—Clinical procedures managed with Standard ANTT will characteristically be technically simple, short in duration (approximately less than 20 minutes), and involve relatively few and small key sites and key parts. Standard ANTT requires a main general aseptic field and non-sterile gloves. The use of critical micro aseptic fields and a non-touch technique is essential to protect key parts and key sites.

- **Surgical ANTT**—Surgical ANTT is demanded when procedures are technically complex, involve extended periods of time, large open key sites or large or numerous key parts. To counter these risks, a main critical aseptic field and sterile gloves are required and often full barrier precautions (Pratt et al, 2007). Surgical ANTT should still utilise critical micro aseptic fields and non-touch technique where practical to do so.

B1.8 Waste management

As there is currently no national definition of clinical waste in Australian, healthcare facilities need to conform to relevant State or Territory legislation and regulations on the management of clinical and related wastes. Healthcare facilities should also refer to AS/NZS 3816.

When handling waste:
- apply standard precautions to protect against exposure to blood and body substances during handling of waste; wash hands following procedure
- segregation should occur at the point of generation
- waste should be contained in the appropriate receptacle (identified by colour and label) and disposed of according to the facility waste management plan
- healthcare workers should be trained in the correct procedures for waste handling.

Regardless of where waste is generated (e.g. isolation rooms/patient versus routine patient-care areas), the principles of determining whether it is to be treated as clinical or general waste remain the same.

B1.8.1 Resources

Standards
- AS/NZ 3816 Management of Clinical and Related Wastes (under revision)
B1.9 Handling of linen

Healthcare facilities must have documented polices on the collection, transport and storage of linen. Healthcare facilities that process or launder linen must have documented operating policies consistent with AS/NZS 4146.

All used linen should be handled with care to avoid dispersal of microorganisms into the environment and to avoid contact with staff clothing. The following principles apply for linen used for all patients (i.e. whether or not transmission-based precautions are required):

- appropriate PPE is worn during handling of soiled linen to prevent skin and mucous membrane exposure to blood and body substances
- used linen is ‘bagged’ at the location of use into an appropriate laundry receptacle
- used linen must not be rinsed or sorted in patient-care areas or washed in domestic washing machines
- linen soiled with body substances should be placed into leak-proof laundry bags for safe transport
- hand hygiene is performed following the handling of used linen.

Clean linen must be stored in a clean dry place that prevents contamination by aerosols, dust, moisture and vermin and is separate from used linen.

Patient items

Domestic-type washing machines must only be used for a patient’s personal items (not other linen). Washing must involve the use of an appropriate detergent and hot water. If hot water is not available, only individual patient loads can be washed at one time. Clothes dryers should be used for drying.

B1.9.1 Resources

Standards

- AS/NZS 4146: Laundry Practice
- AS/NZS 4480.1: Textiles for healthcare facilities and institutions – Medical sheepskins – Product specification and testing.
B2 Transmission-based precautions

Summary

- Transmission-based precautions are applied in addition to standard precautions.
- The aim of instituting early transmission-based precautions is to reduce further transmission opportunities that may arise due to the specific route of transmission of a particular pathogen.
- While it is not possible to prospectively identify all patients needing transmission-based precautions, in certain settings, recognising an increased risk warrants their use while confirmatory tests are pending.
- Section B5.2 (see page 165) outlines recommended precautions for specific infectious agents.

Patient-care tip

When transmission-based precautions are applied during the care of an individual patient, there is potential for adverse effects such as anxiety, mood disturbances, perceptions of stigma and reduced contact with clinical staff. Clearly explaining to patients why these precautions are necessary may help to alleviate these effects.

Evidence supporting practice

The majority of the recommendations in this section have been adapted from:

Further review of the evidence concerning certain aspects of implementation of transmission-based precautions allowed the development of recommendations and good practice points specific to the Australian context. Literature reviews conducted as part of the development of these guidelines or that were released during the guideline development process identified the following:

- good quality evidence on the use of alcohol-based hand rubs in reducing transmission of infectious agents
- a lack of human clinical trials into the benefit of P2 respirators in reducing the risk of transmission of influenza
- a paucity of studies evaluating the effectiveness of negative pressure rooms in reducing the transmission of infectious agents in health care settings.

---

11 These guidelines were selected based on analysis using the AGREE tool, which ensures that guidelines have been developed in a rigorous, transparent and robust manner. This process is discussed in detail in Appendix 2.

12 Due to a paucity of evidence or low quality evidence some systematic reviews were not used to draft recommendations. The reports of those reviews that were used are available from the NHMRC upon request.
B2.1 Application of transmission-based precautions

B2.1.1 What are the risks?

Transmission of infectious agents can occur in a number of ways.

- **Indirect or direct contact transmission**—when healthcare worker hands or clothing become contaminated, patient-care devices are shared between patients, infectious patients have contact with other patients, or environmental surfaces are not regularly decontaminated.

- **Droplet transmission**—when healthcare workers' hands become contaminated with respiratory droplets and are transferred to susceptible mucosal surfaces such as the eyes, when infectious respiratory droplets are expelled by coughing, sneezing or talking, and come into contact with another's mucosa (eyes, nose or mouth), either directly into or via contaminated hands.

- **Airborne transmission**—when attending healthcare workers or others inhale small particles that contain infectious agents.

Figure B2.1: Transmission of infectious agents

Source: Courtesy of Northern Ireland region infection prevention manual, Department of Health, Social Services and Public Safety.
B2.1.2 When are transmission-based precautions applied?

Transmission-based precautions are applied to patients suspected or confirmed to be infected with agents transmitted by the contact, droplet or airborne routes.

The combination of measures used in transmission-based precautions depends on the route(s) of transmission of the infectious agent involved, as outlined in Sections B2.2, B2.3 and B2.4 below. In the acute-care setting, this will involve a combination of the following measures:

- continued implementation of standard precautions
- appropriate use of PPE (including gloves, apron or gowns, surgical masks or P2 respirators, and protective eyewear)
- patient-dedicated equipment
- allocation of single rooms or cohorting of patients
- appropriate air handling requirements
- enhanced cleaning and disinfecting of the patient environment
- restricted transfer of patients within and between facilities.

For diseases that have multiple routes of transmission, more than one transmission-based precaution category is applied. Whether used singly or in combination, transmission-based precautions are always applied in addition to standard precautions. Transmission-based precautions remain in effect for limited periods of time until signs and symptoms of the infection have resolved or according to recommendations from infection control professionals specific to the infectious agent (see Section B5.2, page 165).

The mode of transmission of infectious agents is the same in primary care or office-based practice as it is in the acute-care setting. However, the risk of transmission may differ due to the population groups and the nature of care provided.

Considering the following will help to establish the risk of infection in primary care and office-based practice:

- patient population—this will influence the nature of care required and the type of potential infectious agents (i.e. some populations have a higher incidence of tuberculosis)
- the profile of care—this includes the level of training of staff, what forms of invasive procedures are performed, whether equipment is reprocessed or single use
- local infrastructure—this influences water quality, food availability, access to other health services (i.e. rural vs urban).

In developing policies and procedures for a healthcare facility it is useful to refer to discipline-specific guidelines to inform practice on specialised areas.

An overview of risk-management principles and processes is given in Section A2.

B2.1.3 Environmental cleaning

In acute-care areas where the presence of infectious agents requiring transmission-based precautions is suspected or known, surfaces should be physically cleaned with a detergent solution. A TGA-registered hospital-grade disinfectant should then be used (e.g. 2-step clean or 2-in-1 clean) as outlined in Section B1.4.2). In office-based practice and non-acute-care areas (e.g. long-term care facilities), the risk of contamination, mode of transmission and risk to others should be used to determine whether disinfectants are required.
Crockery and utensils used by patients on transmission-based precautions do not require containment and should be treated in the same manner as those used for non-infectious patients (i.e. washed in a dishwasher). Disposable crockery and utensils are not necessary.

*This section does not provide specific guidance on cleaning. Section B5.1 provides guidance on frequency of cleaning of specific items in low, medium and high-risk settings. Further information on the considerations required when developing cleaning schedules is provided in Section B1.4.2.*

**B2.2 Contact precautions**

**B2.2.1 What are the risks?**

There is clear evidence that certain infectious agents are transmitted by direct or indirect contact during patient care.

Direct transmission occurs when infectious agents are transferred from one person to another person without a contaminated intermediate object or person. For example, blood or other body substances from an infectious person may come into contact with a mucous membrane or breaks in the skin of another person (Rosen 1997; Beltrami et al 2003).

Indirect transmission involves the transfer of an infectious agent through a contaminated intermediate object (fomite) or person. Contaminated hands of healthcare workers have been shown to be important contributors to indirect contact transmission (Boyce & Pittet 2002; Bhalla et al 2004; Duckro et al 2005). Other opportunities for indirect contact transmission include:

- when clothing becomes contaminated after care of a patient colonised or infected with an infectious agent, which can then be transmitted to subsequent patients (Perry et al 2001; Zachary et al 2001)
- when contaminated patient-care devices are shared between patients without cleaning and disinfection between patients (Brooks et al 1992; Desenclos et al 2001; Siegel et al 2008)
- when environmental surfaces become contaminated (see Section B1.4 on routine environmental cleaning and Section B5.1 on frequency of cleaning of specific items).

Direct or indirect contact transmission of microorganisms during patient care is responsible for the majority of healthcare-associated infections in patients and healthcare staff.

**B2.2.2 When should contact precautions be implemented?**

Contact precautions are used when there is a risk of direct or indirect contact transmission of infectious agents (e.g. MRSA, *C. difficile*, or highly contagious skin infections/infestations) that are not effectively contained by standard precautions alone (see Section B1).

The requirements for contact precautions are summarised on page 110. Information about which precautions to apply for specific conditions is given in Section B5.2 (see page 165).

<table>

<tbody>
<tr>
<td><strong>15</strong> Implementation of contact precautions</td>
<td>GPP</td>
</tr>
</tbody>
</table>

In addition to standard precautions, implement contact precautions in the presence of known or suspected infectious agents that are spread by direct or indirect contact with the patient or the patient’s environment.
B2.2.3 How should contact precautions be applied?

The key aspects of applying contact precautions relate to:

- standard precautions
- use of appropriate PPE
- special handling of equipment
- patient placement
- minimising patient transfer or transport.

Hand hygiene and PPE

Effective hand hygiene is particularly important in preventing contact transmission and the 5 moments for hand hygiene outlined in Section B1.1.2 should be followed at all times. When the presence of *C. difficile* or non-enveloped viruses is known or suspected, use of alcohol-based hand rubs alone may not be sufficient to reduce transmission of these organisms (see Section B1.1.3).

Putting on both gloves and gown upon entering the patient-care area helps to contain infectious agents, especially those that have been implicated in transmission through environmental contamination (e.g. VRE, MRSA, *C. difficile*, norovirus and other intestinal tract pathogens, respiratory syncytial virus) (Hall & Douglas 1981; CDC 1995; Evans et al 2002; Bhalla et al 2004; Donskey 2004; Duckro et al 2005; Wu et al 2005). Considerations in selecting a gown appropriate to the situation are outlined in Section B1.2.

A surgical mask and protective eyewear must be worn if there is the potential for generation of splashes or sprays of blood and body substances into the face and eyes.

</tr>
<tr>
<td>• remove gown and gloves and perform hand hygiene before leaving the patient-care area.</td>
<td></td>
</tr>
</tbody>
</table>

Single-use or patient-dedicated equipment

Standard precautions concerning patient-care equipment (see Section B1.5) are very important in the care of patients on contact precautions. If patient-care devices (e.g. blood pressure cuffs, nebulisers, mobility aids) are shared between patients without being reprocessed between uses, they may transmit infectious agents (Brooks et al 1992; Desenclos et al 2001; Rutala & Weber 2008).

<td></td>
</tr>
</tbody>
</table>
Patient placement

A single-patient room is recommended for patients who require contact precautions. Rooms with ensuites and anterooms are preferred (see also C6). Other points relevant to patient placement include the following:

- keep patient notes outside the room
- keep patient bedside charts outside the room
- disinfect hands upon leaving room and after writing in the chart
- keep doors closed
- make sure rooms are clearly signed.

When a single-patient room is not available, consultation with infection control professionals is recommended to assess the various risks associated with other patient placement options (e.g. cohorting).

If it is necessary to place a patient who requires contact precautions in a room with a patient who is not infected or colonised:

- avoid placing these patients with patients who are at increased risk of an adverse outcome from infection (e.g. patients who are immunocompromised, have open wounds or have anticipated prolonged lengths of stay)
- change protective attire and perform hand hygiene between contact with patients in the same room, regardless of whether one or both patients are on contact precautions.

Transfer of patients

Limiting transfer of a patient on contact precautions reduces the risk of environmental contamination. If transfer within or between facilities is necessary, it is important to ensure that infected or colonised areas of the patient’s body are contained and covered. Contaminated PPE should be removed and disposed of and hand hygiene performed before the patient is moved. Clean PPE should be put on before the patient is handled at the destination.

Risk-management case study

**Klebsiella pneumoniae sepsis in a neonatal unit**

During a 7-month period, seven infants in a neonatal unit developed septicaemia from multi-resistant extended spectrum β-lactamase producing Klebsiella pneumoniae, and two babies died. Molecular typing revealed that four of the strains were identical, not all isolates were available for typing. Screening of all babies was not carried out, as it was expected that many would already be colonised, and that babies whose gut was colonised by the bacteria would be the source of infection through the hands of healthcare workers. The outbreak was brought under control by in-service education and improvement of hand hygiene compliance, and wearing of single-use gloves when babies’ nappies were being changed. Nurses were declared to be the advocates for the babies, and the nurse caring for each baby was responsible for ensuring that all attending personnel perform hand hygiene before and after handling the baby, with non-compliance being reported to the infection control team.

Source: Based on Royle et al (1999).
### Eliminating risks
In this situation it is not possible to eliminate the risk entirely, so it must be managed.

### Identifying risks
In this case, the risk has been identified as cross-transmission of *Klebsiella pneumoniae*.

### Analysing risks
The major source of the risk is transmission between neonates by healthcare workers’ hands, with failure to wear gloves when changing nappies, and lack of appropriate hand hygiene practices by some staff members.

### Evaluating risks
The balance of likelihood and consequences identify this as a ‘very high risk’ situation requiring immediate response.

### Treating risks
Immediate measures include implementation of contact precautions, with strict enforcement of hand hygiene, wearing of PPE (e.g. gloves), and provision of in-service education on hand hygiene. Longer-term measures might include increased frequency of environmental cleaning, performance of surveillance cultures, and cohorting of colonised babies, if the outbreak could not be brought under control by immediate measures.

### Monitoring
Changes in rates of infection could be monitored through ongoing surveillance.

## B2.3 Droplet precautions

### B2.3.1 What are the risks?

A number of infectious agents are transmitted through respiratory droplets (i.e. large-particle droplets >5 microns in size) that are generated by a patient who is coughing, sneezing or talking. Transmission via large droplets requires close contact as the droplets do not remain suspended in the air and generally only travel short distances. There is also the potential for infectious agents transmitted by the droplet route to be transmitted by contact.

Droplet precautions are based on evidence that shows that:

- hand hygiene is effective in preventing transmission of viruses and reducing the incidence of respiratory infections both within and outside healthcare settings (Pittet & Boyce 2001; Aiello & Larson 2002; Boyce & Pittet 2002)
- physical interventions are highly effective against the spread of a broad range of respiratory viruses (Jefferson et al 2009; Gralton and McLaws 2009)
- surgical masks protect the wearer from droplet contamination of the nasal or oral mucosa (DoHA 2006)
- physical proximity of less than one metre has long been associated with an increased risk for transmission of infections via the droplet route (e.g. *N. meningitidis* and group A streptococcus (Hamburger & Robertson 1948; Feigin et al 1982)
- placing masks on coughing patients can also prevent infected patients from dispersing respiratory secretions into the air (Siegel et al 2007).

### B2.3.2 When should droplet precautions be implemented?

Droplet precautions are intended to prevent transmission of infectious agents spread through close respiratory or mucous membrane contact with respiratory secretions. Because these microorganisms do not travel over long distances, special air handling and ventilation are not required. Infectious agents for which droplet precautions are indicated include respiratory syncytial virus (RSV) and meningococcus.
The requirements for droplet precautions are summarised on page 110. Information about which precautions to apply for specific conditions is given in Section B5.2 (see page 165).

**Recommendation**

<td>C</td>
</tr>
</tbody>
</table>

### B2.3.3 How should droplet precautions be applied?

The key aspects of applying droplet precautions relate to:

- standard precautions
- use of appropriate PPE
- special handling of equipment
- patient placement
- minimising patient transfer or transport.

**Hand hygiene and personal protective equipment**

Droplet transmission is, technically, a form of contact transmission and some infectious agents transmitted by the droplet route may also be transmitted by contact (Siegel et al 2007). Hand hygiene is therefore an important aspect of droplet precautions and the 5 moments for hand hygiene outlined in Section B1.1.2 should be followed.

There is insufficient evidence to support the use of P2 respirators for reducing the risk of infections transmitted by the droplet route. Although surgical masks do not protect the wearer from infectious agents that are transmitted via the airborne route, surgical masks that meet Australian Standards are fluid resistant and protect the wearer from droplet contamination of the nasal or oral mucosa (DoHA 2006). The mask is generally put on upon room entry, with hand hygiene practiced before putting on the mask and after taking off the mask.

More studies are needed to improve understanding of droplet transmission under various circumstances. The CDC isolation guidelines (Siegel et al 2007) specify that masks should be put on when the healthcare worker is ‘a short distance from a patient’, giving a distance of 1 metre around the patient as an example of what is meant by this, but also stating that it may be prudent to put on a mask upon entry into the patient’s room, especially when the patient has violent, frequent coughing and sneezing or when exposure to emerging or highly virulent pathogens is likely.

There is insufficient evidence to recommend the routine use of protective eyewear with individuals on droplet precautions, unless there is a risk of splashes or spray to the mucosa (see Section B1.2). Goggles provide reliable eye protection from respiratory droplets from multiple angles.

Emerging evidence on droplet transmission will be monitored as a part of the ongoing review process.

**Recommendation**

</tr>
</tbody>
</table>
Placement of patients on droplet precautions

Placing patients on droplet precautions in a single-patient room reduces the risk of patient-to-patient transmission. When single-patient rooms are in short supply, the following principles apply in decision-making on patient placement:

- prioritise patients who have excessive cough and sputum production for single-patient room placement
- place together in the same room (cohort) patients who are infected with the same pathogen and are suitable roommates.

If it becomes necessary to place patients who require droplet precautions in a room with a patient who does not have the same infection:

- avoid placing patients on droplet precautions in the same room with patients who have conditions that may increase the risk of adverse outcomes from infection or that may facilitate transmission (e.g. those who are immunocompromised, have anticipated prolonged lengths of stay, have cystic fibrosis, cardiac conditions or muscular dystrophy)
- ensure that patients are physically separated (> 1 metre apart) from each other and draw the privacy curtain between beds to minimise opportunities for close contact.

In all cases, the importance of respiratory hygiene and cough etiquette should be explained to patients on droplet precautions (see Section B1.6).

In primary care and other office-based practice, examples of appropriate implementation of droplet precautions include segregation in waiting rooms for patients with violent or frequent coughing, and the availability of tissues, alcohol-based handrub and a waste bin so that patients can practice respiratory hygiene and cough etiquette.

Transfer of patients on droplet precautions

When transfer of a patient on droplet precautions within or between facilities is necessary, there is the potential for other patients and healthcare workers to come in contact with infectious agents when the patient coughs or sneezes. This can be addressed by asking the patient to wear a mask while they are being transferred and to follow respiratory hygiene and cough etiquette. Children should wear a correctly fitting mask when they are outside an isolation room. The child's oxygen saturation should be monitored.

Risk-management case study

Influenza in a long-term care facility

A cluster of cases of influenza occurred in a long-term care facility, which were observed after a group activity involving dancing was held in the dining room prior to the midday meal. It was observed that a number of residents who had been unwell had attended the group activity and had sat at the dining tables. Due to the lack of waste receptacles in the dining room, used tissues were placed on the dining room tables. It was also noticed that a number of residents remained in the vicinity of the dining room post activity as their rooms were a short distance from the dining room. The shared bathrooms were at the other end of the corridor so it was not known whether hand hygiene was performed prior to meals or the event. Residents reported signs and symptoms consistent with influenza at least 2 days following the event, which was later confirmed by rapid diagnostic test from four patients and two staff members. The vaccination coverage of the staff was 41.7%. None of the staff members with influenza symptoms who had assisted in the group activities had been immunised.
In this situation, it is not possible to eliminate the risk immediately, so it must be managed.

Identifying risks

In this case, the risk has been identified as cross-transmission of influenza.

Analysing risks

One source of transmission is the assembling of large numbers of residents in a confined area in which close contact droplet transmission occurred such as sneezing, coughing or talking. In addition the lack of waste receptacles available would have hindered immediate disposal of infectious waste material. Healthcare workers or other residents may have had indirect contact with influenza droplets from the dirty tissues lying on the table, particularly if any of the other people disposed of the tissues later. The lack of hand hygiene facilities in the immediate vicinity could have resulted in poor hand hygiene compliance, with staff or residents not decontaminating their hands prior to eating or after sneezing or coughing. Low levels of staff immunisation also contributed to the spread of the infection.

Evaluating risks

The balance of likelihood and consequences identify this as a ‘very high risk’ situation requiring immediate response.

Treating risks

Immediate measures may include:

• waste receptacles being made available in a common area, so people can dispose of tissues immediately after use
• the provision of ABHR so residents (and staff) can decontaminate their hands prior to eating, handling food or coughing and sneezing.

Other measures may include:

• education of staff and residents on the importance of hand hygiene, respiratory hygiene and cough etiquette
• immunisation of residents and staff and asking sick staff members to stay at home;
• education of residents, that if they feel unwell, to avoid participating in group activities until they feel better
• displaying posters and signage on hand hygiene and respiratory hygiene around the facility on an ongoing basis.

Monitoring

Immunisation rates among staff and residents could be monitored, as well as monitoring the difference in case numbers from previous influenza outbreaks and outbreaks after the measures have been put in place.

B2.4 Airborne precautions

B2.4.1 Why are airborne precautions important?

Certain infectious agents are disseminated through airborne droplet nuclei or small particles in the respirable size range that remain infective over time and distance.

Airborne precautions are based on evidence that shows that:

• the use of P2 respirators prevents the inhalation by healthcare workers of small particles that may contain infectious agents transmitted via the airborne route (DoHA 2006)
• the use of negative pressure rooms may also reduce the transmission of infection
• wearing of correctly-fitted surgical masks by coughing patients prevents dispersal of respiratory secretions into the air (Siegel et al 2007).

B2.4.2 When should airborne precautions be implemented?

Airborne precautions prevent transmission of microorganisms that remain infectious over time and distance when suspended in the air. These agents may be inhaled by susceptible individuals who have not had face-to-face contact with (or been in the same room as) the infectious individual.
Infectious agents for which airborne precautions are indicated include measles (rubeola), chickenpox (varicella) and *M. tuberculosis*.

The requirements for airborne precautions are summarised on page 110. Information about which precautions to apply for specific conditions is given in Section B5.2 (see page 165).

### B2.4.3 How should airborne precautions be applied?

The key aspects of applying airborne precautions relate to:

- standard precautions, including respiratory hygiene and cough etiquette (see Section B1.6)
- use of appropriate PPE (particularly correctly-fitted respirators)
- minimising exposure of other patients and staff members to the infectious agent.

Specialist procedural areas should refer to their discipline-specific guidelines for detailed advice on applying airborne precautions relevant to the field of practice.

#### Personal protective equipment

When there is a high probability of airborne transmission due to the infectious agent or procedure, sound scientific principles support the use of P2 respirators to prevent transmission (see also Table B1.6; page 52). Respirators are designed to help reduce the wearer’s respiratory exposure to airborne contaminants such as particles, gases or vapours. P2 respirators are appropriate for the majority of airborne precautions encountered in healthcare facilities. There is a range of respiratory protective equipment outlined in AS 1715:2009, which provide differing levels of protection dependant upon the nature of the microorganism, the mode of transmission and procedure being undertaken.

The need for PPE varies with the condition in question and the immune status of the healthcare worker. For example, staff members known to be immune to the relevant infectious agent are not required to wear a P2 respirator. For high-risk procedures such as bronchoscopy where the risk of droplet and airborne infection is high, a P2 respirator should be worn if the infectious status of the patient is unknown or unconfirmed.

#### P2 respirators – fit testing and checking

In order for a P2 respirator to offer the maximum desired protection it is essential that the wearer is properly fitted and trained in its safe use. A risk-management approach should be applied to ensure that staff working in high-risk areas are fit tested and are aware of how to perform a fit check.

#### Fit testing

The purpose of fit testing is to identify which size and style of P2 respirator is suitable for an individual, and to ensure that it is worn correctly. It also provides an opportunity to ensure healthcare workers are properly trained in the correct use of the mask.
Fit testing should be performed:

- at the commencement of employment for employees who will be working in clinical areas where there is a significant risk of exposure to infectious agents transmitted via the airborne route—assessment of the significance of risk will involve consideration of the location (e.g. risk is higher in an intensive care unit) and activities to be undertaken (e.g. a physiotherapist performing induced sputum is at risk of exposure to infectious aerosols);
- when there is a significant change in the wearer's facial characteristics that could alter the facial seal of the respirator (e.g. significant change in body weight, facial surgery); and
- at regular intervals—AS1715:2009 recommends annual fit testing. Healthcare facilities should ensure that they have a respiratory protection program that regularly evaluates the risk to which healthcare workers are exposed and determines which employees are required to undertake fit testing.

Employers must ensure that their employees have the medical ability to wear a respirator. Medical evaluations are required for both positive pressure and negative pressure respirators.

There are two types of facial fit test—qualitative and quantitative. Qualitative fit tests are fast and simple but can be influenced by the wearer. Quantitative fit tests require the use of specialised equipment used by a trained operator. AS/NZS 1715:2009 outlines the method by which fit testing is conducted.

**Fit checking**

Healthcare workers must perform fit checks every time they put on a P2 respirator to ensure it is properly applied. No clinical activity should be undertaken until a satisfactory fit has been achieved. Fit checks ensure the respirator is sealed over the bridge of the nose and mouth and that there are no gaps between the respirator and face. Healthcare workers must be informed about how to perform a fit check.

The procedure for fit checking includes (see Figure B2.2):

- placement of the respirator on the face
- placement of the headband or ties over the head and at the base of the neck
- compressing the respirator to ensure a seal across the face, cheeks and the bridge of the nose
- checking the positive pressure seal of the respirator by gently exhaling. If air escapes, the respirator needs to be adjusted
- checking the negative pressure seal of the respirator by gently inhaling. If the respirator is not drawn in towards the face, or air leaks around the face seal, readjust the respirator and repeat process, or check for defects in the respirator.

The manufacturer’s instructions for fit checking of individual brands and types of P2 respirator should be referred to at all times.

Healthcare workers who have facial hair (including a 1–2 day beard growth) must be aware that an adequate seal cannot be guaranteed between the P2 respirator and the wearer’s face.
Wearing a P2 respirator

Considerations when using a P2 respirator include (DoHA 2006):

- if a good facial seal cannot be achieved (e.g. the intended wearer has a beard or long moustache), an alternative respirator such as a powered air-purifying respirator (PAPR) should be used
- respirators should not be touched while being worn
- respirators should be changed when they become moist
- respirators should never be reapplied after they have been removed
- respirators should not be left dangling around the neck
- hand hygiene should be performed upon touching or disposing of a used respirator.

Respirators should be removed outside the patient-care area and disposed of in a closed receptacle (Siegel et al 2007).
**Recommendation**

**22 Personal protective equipment to prevent airborne transmission**

<table>
<thead>
<tr>
<th>Grade</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
</tr>
</tbody>
</table>

**Wear a correctly fitted P2 respirator when entering the patient-care area when an airborne-transmissible infectious agent is known or suspected to be present.**

**Patient placement**

When patients have a confirmed or suspected airborne-transmissible condition or if nebulisation is to be performed, it is important to place them in an area that can be contained (e.g. placing them in a single room and, providing it is tolerated, asking them to wear a surgical mask while not in a single room, until advised to remove it by attending staff). It is important that the door to the room remains closed and that, where possible, only staff or visitors who are immune to the specific infectious agent enter the room. Non-immune staff should be provided with appropriate PPE.

While there is a paucity of evidence to confirm their effectiveness, the use of correctly serviced/maintained negative pressure rooms may reduce the transmission of airborne infection within healthcare settings (Siegel et al 2007).

Visitors should be restricted and screened by nursing staff, with visitors’ names recorded either in a log book or in the case notes.

**Recommendation**

**23 Placement of patients requiring airborne precautions**

<table>
<thead>
<tr>
<th>Grade</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPP</td>
</tr>
</tbody>
</table>

**Patients on airborne precautions should be placed in a negative pressure room or in a room from which the air does not circulate to other areas.**

Exceptions to this should be justified by risk assessment.

**Transfer of patients**

If transfer of the patient outside the negative pressure room is necessary, asking the patient to wear a correctly fitted surgical mask while they are being transferred and to follow respiratory hygiene and cough etiquette, as well as covering any skin lesions associated with the condition (e.g. chickenpox [varicella]) will reduce the risk of cross-transmission. Children should wear a correctly fitting mask when they are outside an isolation room. The child’s oxygen saturation should be monitored.

**Risk-management case study**

**M. tuberculosis among immunocompromised patients attending outpatient services**

An investigation into the healthcare-associated transmission of *M. tuberculosis* followed reports of two epidemiologically linked patients (Patient 1 and Patient 2) with haematologic malignancies and active pulmonary TB. Subsequently it was found that four oncology patients had spent more than an hour in the same room as Patient 1. Patient 1’s pulmonary TB was not diagnosed for 3 months as clinical findings were attributed to lower respiratory tract infection from other infectious agents or adverse effects of oncology treatments. Patient 1 was not placed on airborne precautions during this period. The investigation found that delayed TB diagnosis in Patients 1 and 2 ultimately resulted in the transmission of *M. tuberculosis* to 19 patients and staff at three hospitals and a residential facility.

**Source:** Based on Malone et al (2004).
**Eliminating risks**

In this situation, it is not possible to eliminate risk, so it must be managed.

**Identifying risks**

In this case, the risk has been identified as cross-transmission of *M. tuberculosis* from a single patient attending a number of outpatient facilities.

**Analysing risks**

The sources of risk are a failure to consider the possibility of tuberculosis and delays in screening and diagnostic tests. These resulted in a lack of transmission-based precautions applied to Patient 1, a source of risk to subsequent patients.

**Evaluating risks**

The balance of likelihood and consequences identify this as a ‘very high risk’ situation requiring immediate response.

**Treating risks**

Immediate measures may include avoidance of potential exposures in outpatient settings, implementation of airborne precautions and treatment of febrile, coughing patients with pulmonary TB. State/territory TB services would also need to be notified, as they would assist in the development of a management plan. Longer-term measures could include implementation of baseline TB screening for immunocompromised patients and protocols to assist with earlier diagnosis of active disease. Further measures would include increasing awareness of tuberculosis generally, educating staff about identifying the high-risk patients for a particular facility, and development of specific protocols, such as ‘cough protocols’.

**Monitoring**

Ongoing surveillance would assist in reducing the risk of subsequent outbreaks. Retrospective review and screening of other contacts and laboratory typing of *M. tuberculosis* isolates to identify unrecognised, linked transmission could also inform future actions.

---

**Measles (rubeola) control in general practice**

The case study in Section A2.2 (see page 30) outlines a risk assessment approach to airborne precautions in the primary care setting.

**B2.5 Putting it into practice**

**Individual actions for reducing risk**

- Consult with infection control professionals to ensure that appropriate transmission-based precautions are applied and that they remain in place until the risk of transmission of the infectious agent has passed
- Remember that transmission-based precautions are applied AS WELL as standard precautions
- Advise patients why particular measures are needed to control infection (see above)
- Become familiar with local policy on appropriate PPE, and when it should be put on and taken off, when attending patients on transmission-based precautions
- Make sure you know which type of mask is needed in different situations and how to check that they are properly fitted
- Always contain or cover the infected or colonised areas of a patient on contact precautions before moving them from one patient-care area to another
- Explain the purpose and process of respiratory hygiene and cough etiquette to patients on droplet precautions
- Ask patients on droplet or airborne precautions to wear a surgical mask if they are being moved from one patient-care area to another
- If patients are moved to a single-patient room (contact or droplet precautions) or negative pressure room (airborne precautions) explain why this is necessary to prevent transmission of infection
- Make sure you are fully immunised against vaccine-preventable diseases as recommended in the Australian Immunisation Handbook
Involving patients in their care

The following information may be provided to patients to assist them in becoming involved in identifying and reducing risks.

- When a patient has a condition that can easily be transmitted to others, extra measures beyond normal practices to prevent and control infection are needed—these are for everybody’s safety.

- Hand hygiene is the most important aspect of preventing the spread of infection. This means everyone, including visitors, should perform hand hygiene after any contact with the patient or environment that could lead to contamination.

- Hand hygiene is also important for the patient, especially after activities when hands come in contact with possible sources of infection (such as blowing your nose, going to the toilet, touching infected wounds).

- ‘Respiratory hygiene and cough etiquette’ is an important part of reducing the risk of infection to others. This includes covering the mouth with a tissue when coughing or sneezing, disposing of the tissue in the nearest waste receptacle and performing hand hygiene.

- Healthcare workers wear gloves and gowns to limit the spread of infection.

- For some infections, the patient needs to wear a mask so that they do not infect others (for example when they are sneezing or coughing), especially if they are moving between patient-care areas.

- Regular cleaning of the patient’s room and objects around them helps to prevent the spread of infection.

- If a healthcare worker might be splashed by the patient’s body substances, he or she should wear face protection.

- Any piece of equipment that might come in contact with infectious agents is thrown away or cleaned and disinfected before it is used again.

- For some types of infection, it is necessary to place patients in a single room or to keep them more than a metre away from other patients. Sometimes patients with the same infection are placed in a room together.

- It’s okay to question a healthcare worker about whether they have taken measures to prevent infection (like performing hand hygiene, wearing a gown or mask or using clean equipment).

**Notes:**

✓ Essential component of transmission-based precautions

♣ Surgical mask required if infectious agent isolated in sputum

✩ As required — Gloves to be worn whenever there is the potential of direct or indirect contact with blood or body substances

  - Gowns to be worn for procedures when there is the potential of direct or indirect contact to body substances
  - Face and eye protection to be worn when there is the potential of exposure to splashes or sprays to mucosa (including during aerosol-generating procedures)

* Visitors should be given instruction about correct procedures when transmission-based precautions are applied and given appropriate resources to support them in meeting these requirements.

* If staff or visitor HAVE HAD chickenpox / measles in the past or vaccination for these diseases, mask, gown and gloves are not required

**Environmental cleaning** has not been addressed in this table but it is an essential component of infection prevention and control. For further guidance please refer to section B1.4 For more detail on specific diseases please refer to Section B5.2.

B3 Management of multi-resistant organisms and outbreak situations

Summary

- Effective hand hygiene is the most important measure to prevent and control the spread of multi-resistant organisms (MROs). Rigorous adherence to hand hygiene is also integral to any outbreak control and management program.
- The application of transmission-based precautions is particularly important in containing MROs such as methicillin-resistant Staphylococcus aureus (MRSA), vancomycin-resistant enterococci (VRE), and multi-resistant Gram-negative bacteria (MRGN) (see Section B3.1).
- Transmission-based precautions are also an integral part of outbreak management (see Section B3.2).
- Specific precautions required for each infectious agent are listed in Section B5.2 (see page 165).

Patient-care tip

When a patient is infected or colonised with an MRO or involved in an outbreak, there is potential for adverse effects such as anxiety, mood disturbances, perceptions of stigma and reduced contact with clinical staff. Clearly explaining to patients the measures being undertaken and why they are necessary may help to alleviate these effects.

Evidence supporting practice

The majority of the recommendations in this section have been adapted from United States Centers for Disease Control and Prevention (CDC) Management of Multidrug-Resistant Organisms in Healthcare Settings (2006).13

Further review of the evidence concerning the management of MROs allowed the development of recommendations and good practice points specific to the Australian context. Literature reviews conducted as part of the development of these guidelines or that were released during the guideline development process identified the following:

- good quality evidence on the use of alcohol-based hand rubs in reducing transmission of MROs
- a paucity of evidence regarding the use of PPE for preventing the transmission of MRSA and VRE
- a paucity of prospectively designed experimental studies into the effectiveness of patient isolation in reducing transmission of MROs
- lack of evidence regarding the value of screening for MROs in the absence of implementation of other infection control measures
- a paucity of evidence concerning routine screening of healthcare workers for MRSA colonisation.

---

13 These guidelines were selected based on analysis using the AGREE tool, which ensures that guidelines have been developed in a rigorous, transparent and robust manner. This process is discussed in detail in Appendix 2.
B3.1 Management of multi-resistant organisms

B3.1.1 What are the risks?

MROs, which are predominantly bacteria, are resistant to multiple classes of antimicrobial agents. Antibiotic resistance increases the morbidity and mortality associated with infections, and contributes to increased costs of care due to prolonged hospital stays and other factors, including the need for more expensive drugs (Struelens 1998). A major cause of antibiotic resistance is the exposure of a high-density, high-acuity patient population in frequent contact with healthcare workers to extensive antibiotic use, along with the attendant risk of cross-infection (Gold & Moellering 1996; Christiansen et al 2008).

For the purpose of these guidelines, MROs are taken to include:
- all methicillin-resistant Staphylococcus aureus—MRSAs cause up to a third of hospital-acquired bloodstream infections (Christiansen et al 2008), with mortality from BSI ranging from 10% to 50% according to the setting (Herwaldt 1999)
- all vancomycin-resistant enterococci with mobile resistance determinants (e.g. VanA, VanB)—the ratio of invasive VRE infection to colonisation appears to be proportionately lower than that of MRSAs (Christiansen et al 2008)
- a range of Gram-negative bacteria with multiple classes of drug resistance or resistant mechanisms to critically important antibiotics—highly transmissible resistance is a particular feature of antibiotic resistance among the Gram-negative bacteria, especially the Enterobacteriaceae. Multi-drug resistance is also common and increasing among non-fermenting Gram-negative bacteria (e.g. Pseudomonas aeruginosa and Acinetobacter baumannii) and a number of strains have now been identified that exhibit resistance to essentially all commonly used antibiotics. These organisms are associated with treatment failure and increased morbidity (Christiansen et al 2008).

A two-level approach is necessary for the prevention and control of MROs. This involves implementation of:
- core strategies for MRO prevention and control in any situation where MRO infection or colonisation is suspected or identified (see Section B3.1.2)
- organism-based or resistance mechanism-based approaches if incidence or prevalence of MROs are not decreasing despite implementation of the core strategies (see Section B3.1.3).

In the event of an MRO outbreak, investigation and control/containment should be conducted as outlined in Section B3.2.

The best practices in these guidelines are based on the assumption that healthcare settings already have basic infection prevention and control systems in place. If this is not the case, healthcare settings will find it challenging to implement the practices recommended for the management of MRSA and VRE. These settings must work with organisations that have infection prevention and control expertise, such as academic health science centres, regional infection control networks, public health units that have professional staff certified in infection prevention and control and local infection prevention and control associations to develop evidence-based programs (PIDAC 2007).
B3.1.2 Core strategies for MRO prevention and control

Successful control of MROs is based on a combination of interventions. These involve continued rigorous adherence to hand hygiene, appropriate use of PPE and implementation of specific transmission-based precautions (isolation of infected or colonised patients, increased environmental cleaning and patient-dedicated equipment) until patients are culture-negative for a target MRO or have been discharged from the facility.

In non-acute healthcare settings, general measures of infection control (particularly hand hygiene by both patients and healthcare workers) may be enough to prevent transmission. However, contact precautions, such as gowns and gloves, may be necessary if the patient is heavily colonised or there is known continuing transmission. Local guidelines and circumstances should determine practice in settings where the patient population is vulnerable (Matlow & Morris 2009).

Organisational measures—such as staff education on prevention and management of MRO transmission, antibiotic stewardship program, and appropriate response to active surveillance cultures—are discussed in Part C.

Hand hygiene

MROs can be carried from one person to another via the hands of a healthcare worker. Contamination can occur during patient care or from contact with environmental surfaces in close proximity to the patient, particularly when patients have diarrhoea and the reservoir of the MRO is the gastrointestinal tract. Effective hand hygiene is therefore the most important measure to prevent and control the spread of MROs. Alcohol-based hand rub of at least 70% v/v ethanol or equivalent has been shown to be effective against MRSA and VRE (Picheansathian 2004).

Personal protective equipment

Both direct patient contact (e.g. routine patient care) and indirect contact (e.g. involving environmental contamination) can lead to contamination of the healthcare worker's hands and clothing. Appropriate use of gloves has been found to be as effective a strategy as patient isolation in containing MROs, particularly when isolation may not be feasible (Trick et al 2004; Bearman et al 2007). Glove use is more effective when combined with wearing of gowns (Puzniak et al 2002; Srinivasan et al 2002; Hayden et al 2008). Section B1.2.3 provides guidance on the selection of an appropriate gown and Section B1.2.5 on selection of gloves.

Isolation

Placing colonised or infected patients in single rooms, cohort rooms or cohort areas as a component of a multifaceted infection control policy can reduce acquisition rate and infection with MROs in acute-care settings. Cohorting patients with the same strain of MRO has been used extensively for managing outbreaks of specific MROs, including MRSA, VRE, extended spectrum beta-lactamase (ESBL)-producing bacteria, and \textit{Pseudomonas aeruginosa}. However, it is not always appropriate to cohort patients with the same MRO species if they have a different resistance mechanism or phenotype (e.g. if one has a community-acquired strain of likely panton-valentine leukocidin (PVL)-positive MRSA and the other has a hospital-acquired strain of MRSA).

In long-term care facilities, isolation and cohorting may not be possible, so hand hygiene with appropriate routine use of gloves for individual resident and environmental contact is preferred (Trick et al 2004).

Due to the varying nature of healthcare facilities, it is not feasible to provide a generic policy on the movement of patients with MROs. This needs to occur at a local level and be relevant to the patient's treatment plan. These policies should not limit access to treatment and should consider the social implications of managing a patient with an MRO.
Environmental cleaning

In acute-care areas where the risk of patient vulnerability and risk of cross infection due to the presence of an MRO is high, contact precautions should be followed. This will require all patient surrounds and frequently touched objects (e.g. bedrails, trolleys, bedside commodes, doorknobs, light switches or tap handles, ensuite facilities) to be cleaned with a suitable detergent and disinfected with a TGA-registered hospital grade disinfectant.

As outlined in Section B1.4 this process must involve either:

- a 2-step clean, which involves a physical clean using detergent solution followed by use of a chemical disinfectant
- a 2-in-1 clean in which a combined detergent/disinfectant wipe or solution is used and mechanical/manual cleaning action is involved.

Sole reliance on a disinfectant without mechanical/manual cleaning is not recommended.

Patient equipment

Standard precautions concerning patient-care equipment are very important in the care of patients with MROs. Patient-care devices (e.g. electronic thermometers) may transmit infectious agents if devices are shared between patients. To reduce the risk of transmission, disposable or patient-dedicated equipment is preferred. Section B1.5 provides more detailed information on reusable instruments and equipment.

Monitoring

Monitoring of the incidence of target MRO infection and colonisation should continue after these interventions are implemented. If rates do not decrease, more interventions may be needed to reduce MRO transmission as outlined in Section B3.1.3.

Recommendation

24  Implementation of core strategies in the control of MROs (MRSA, MRGN, VRE)  Grade C

Implement transmission-based precautions for all patients colonised or infected with an MRO, including:

- performing hand hygiene and putting on gloves and gowns before entering the patient-care area;
- using patient-dedicated or single-use non-critical patient-care equipment
- using a single-patient room or, if unavailable, cohorting patients with the same strain of MRO in designated patient-care areas
- ensuring consistent cleaning and disinfection of surfaces in close proximity to the patient and those likely to be touched by the patient and healthcare workers.

Patient-care tip

When patients are placed on transmission-based precautions due to infection or colonisation with an MRO, efforts should be made to ensure patients continue to receive adequate medical care, and to counteract potential psychological adverse effects of isolation such as anxiety and depression, and feeling of stigmatisation.
B3.1.3 Organism-specific approach

When the incidence or prevalence of MROs is not decreasing despite implementation of the core strategies outlined above, further measures to control transmission need to be considered. A risk management approach focuses on:

- the type of MRO (e.g. prioritisation of available isolation facilities according to MRO)
- the healthcare area (e.g. intensive care or haematology/oncology units have higher risks of transmission)
- patient factors (e.g. whether the consequences of infection are severe)
- available resources (e.g. whether screening a certain patient population is feasible)
- whether interventions to interrupt transmission are available (e.g. decolonisation for MRSA).

Further measures may include:

- **targeted screening**—timely active screening to identify colonised patients combined with the use of contact precautions for the care of colonised patients has been followed by a significant reduction in the rates of both colonisation and infection of patients with MRSA (Calfee & Farr 2002; Pop-Vicas & D-Agata 2005). Screening involves collecting specimens from the patient and subsequent laboratory analysis of these samples. In a risk assessment approach to screening, considerations include the endemicity of the MRO, the prevalence of MRO infection, and the likelihood of MRO carriage. Clinicians and the infection control professional should be informed of both negative and positive screening results promptly. If screening returns a positive sample, contact precautions should be applied and appropriate use of isolation and cohorting facilities should be implemented.

- **decolonisation**—interventions may be topical—whole body washes (using chlorhexidine) and topically applied antimicrobial agents (e.g. mupirocin); systemic—orally administered antibiotics (tetracyclines, fusidic acid, ciprofloxacin, rifampin and trimethoprim-sulfamethoxazole); and combinations of systemic and topical therapy.

- **surveillance and timely feedback**—increased surveillance may be appropriate to monitor the effect of interventions designed to control particular MROs. Surveillance information should be fed back to health care workers and facility management promptly.

**Screening**

Currently there is no consensus nationally or internationally about the most appropriate manner to conduct screening for MROs. Control measures specific to local factors should be determined and endorsed by the healthcare facility management structure, and the screening protocols for MROs should be influenced by the:

- local prevalence of the MRO
- the reason for admission of the patient
- the risk status of the unit to which they are admitted
- the likelihood that the patient is carrying an MRO.

As a minimum standard to reduce the risk of transmission of MROs, it is recommended that the following approaches to screening be implemented. Expert direction and resources allocation is required for effective MRO screening.

The decision to screen for VRE and MRGN is optional and should be made on the basis of local epidemiology, necessity for screening and resource factors. The following tables provide guidance for screening based on patient risk factors for these organisms. Other risk groups may be defined by local experience, based on screening initiatives or outbreak epidemiology.
For example, some facilities have found that screening patients who are recent hospital admissions from international facilities into Australian facilities have increasingly been shown to be positive for MRGN. While this is an area for future research, currently, healthcare facilities could consider screening these patients on admission, particularly in areas where MROs are found to be prevalent in transferred patients.

Table B3.1: Suggested approach to screening for MRSA

<table>
<thead>
<tr>
<th>Organism</th>
<th>Screen who</th>
<th>Screen when</th>
<th>Sample collection</th>
</tr>
</thead>
</table>
| MRSA     | • Patients at high risk of carriage:  
- those who are known to have been previously infected or colonised with MRSA  
- frequent re-admissions to any healthcare facility  
- transfers from other acute care facilities  
- residence in long term care facilities  
- patients with chronic wounds  
- recent inpatients at hospitals known or likely to have a high prevalence of MRSA  
- locales or populations where community-acquired strains of MRSA are prevalent  
- Healthcare workers epidemiologically linked to single-strain outbreak in healthcare facility  
- Patients in high-risk units  
- ICU/high dependency unit (admission and discharge)  
- Spinal unit  
- Burns unit  
- Pre-operative clinics  
- Patients with planned prosthetic surgery (joint replacement, cardio-thoracic surgery)  
- All patients on admission, discharge and once weekly  | • Screened routinely at the time of admission unless they are being admitted directly to isolation facilities and it is not planned to attempt to clear them of MRSA carriage  
• After confirmation of epidemiological evidence  
• 2 weeks after decolonisation therapy  | • Multiple sites including one from the nose and a mucosal surface  
• Reasonable sites to swab include nares, skin lesions and wounds, sites of catheters, catheter urine, groin/perineum, tracheostomy and other skin break in all patients, and sputum from patients with a productive cough  
• Where maximum sensitivity is required, consideration should be given to adding a throat swab. The umbilicus should be sampled in all neonates |

Management

Apply stringent hand hygiene, contact precautions (gloves and gown) and core strategies outlined in B.3.1.2 including isolating and cohorting patients, increased environmental cleaning and dedicated patient equipment.

Patients positive for MRSA have an electronic alert placed on their case record for easy identification on readmission. Consider topical plus/minus systemic decolonisation for:

- Healthcare workers epidemiologically linked to transmission
- Patients having prolonged hospitalisation
- Patients with chronic conditions likely to be readmitted (e.g., haemodialysis).
- Patients before undergoing high-risk elective surgery such as cardiac and implant surgery.

**Management**

**Staff screening and decolonisation is not recommended for VRE and MRGN**

Apply stringent hand hygiene, contact precautions (gloves and gown) and core strategies outlined in B.3.1.2 including isolating, cohorting, increased environmental cleaning and dedicated patient equipment. Patients positive for VRE or MRGN should have an electronic alert placed on their case record for easy identification on readmission.
MRO clearance

Based on the 2005 Multi-Resistant Organism Screening and Clearance Recommendations the following criteria should be satisfied prior to certifying that a patient has cleared a particular MRO:

- more than 3 months elapsed time from the last positive specimen
- all wounds healed, no indwelling medical devices present
- no exposure to any antibiotic or antiseptic body wash for at least 2 weeks prior to screening
- in the case of MRSA, no exposure to specific anti-MRSA antibiotic therapy in the past three months
- consecutive negative screens from above screening sites on two separate occasions OR evaluation of a single set of screening swabs with a broth amplification technique.

Some patients with VRE may appear to ‘clear’ with time but relapse with antibiotic therapy. Where VRE or MRGN are prevalent, admission and interval screening in specialised units is an important way to detect new or relapsed VRE or MRGN colonisation.

These criteria are based on evidence related to MRSA. It is recognised that there is variation in clearance methods between jurisdictions, but currently there is insufficient evidence to recommend the most effective method of demonstrating clearance of a particular MRO. This is an area that warrants further research. The important issue appears to be sampling the patient on more than two occasions separated in time. This period should not be less than 3 weeks but is typically months.

Examples of successful approaches

With an incidence rate of 1.09 per 100,000 population in 2006, Western Australia (WA) has consistently reported low rates of acquisition of MRSA compared to other states in Australia (Ferguson 2007). Tables B3.3 and B3.4 provide examples of approaches that have been successful in reducing rates of cross-transmission in hospitals in WA. It is acknowledged that approaches will vary across jurisdictions, depending on the setting (e.g. available resources and access to laboratory techniques).

B3.1.4 Antibiotic stewardship

Over the last 40 years, the prevalence of MROs such as MRSA has risen alarmingly, initially mainly in hospitals but now increasingly in the community. There is good evidence that overall rates of antibiotic resistance correlate with the total quantity of antibiotics used, as determined by the number of individuals treated, prior exposure and the average duration of each treatment course. Some antibiotics promote the development of resistance more readily than others, depending in part on the breadth of their antibacterial spectrum. In individuals, the risk of colonisation and infection with MROs correlates strongly with previous antibiotic therapy.

Unnecessary antibiotic use for self-limiting or non-infective illness and inappropriate antibiotic choice, dose or duration of therapy drives the selection of resistant bacteria, disrupts normal bacterial flora and increase the risk of colonisation with resistant organisms. There is a lag period between acquisition of an MRO and its detection; during this period, the infection may spread between patients if risk factors for acquisition are not considered carefully. Clinicians may be under pressure to prescribe broad-spectrum agents against likely pathogens in an environment where MROs are common, thereby further increasing the development of resistant organisms.

As many as 25–50% of antibiotic regimens prescribed in hospitals may be inappropriate. The reasons for the continued unnecessary and/or inappropriate use of antibiotics, in the face of increasing antibiotic resistance and availability of well-established evidence-based treatment guidelines, are varied.

Antibiotic stewardship programs involve a systematic approach to optimising the use of antibiotics (see Section C5). Effective hospital antibiotic stewardship programs have been shown to decrease antibiotic use and improve patient care. Along with infection control, hand hygiene and surveillance, antibiotic stewardship is considered a key strategy in local and national programs to decrease MROs and HAIs.

B3.1.5 Risk-management case study

VRE outbreak in a large tertiary-care referral hospital

Two months after the first index case of VRE was detected in the intensive care unit of a large teaching hospital, 68 patients had become either infected or colonised with an epidemic strain of vanB vancomycin-resistant Enterococcus faecium, despite standard infection control procedures. Subsequently, 169 patients in 23 wards were found to be colonised with a single strain of vanB vancomycin-resistant E. faecium. Introducing additional control measures rapidly brought the outbreak under control. Hospital-wide screening found 39 previously unidentified colonised patients, with only 7 more non-segregated patients being detected in the next 2 months. The outbreak was terminated within 3 months due to a well-resourced, multifaceted approach.

B3.2 Outbreak investigation and management

When there are more cases of infection with the same organism than would normally be expected in one area or period of time, this constitutes an outbreak.

An outbreak may be defined as:
- occurrence of more cases of disease than expected in a given area among a specific group of people over a particular period of time
- two or more linked cases of the same illness.

Commonly detected outbreaks involve:
- MRSA (see Section B3.1.3);
- aminoglycoside or multi-resistant enterobacteriaceae or pseudomonads
- diarrhoeal pathogens (e.g. *Salmonella*, *Campylobacter*, norovirus)
- respiratory pathogens (e.g. influenza, RSV)
- measles (rubeola), chickenpox (varicella)
- hepatitis A
- *C. difficile* enterocolitis
- Legionnaires’ disease.

This section gives principles and overall guidance for managing an outbreak. For specific guidance on particular infections, please refer to national guidelines related to management of that infection.

B3.2.1 Outbreak investigation and management

A suspected outbreak may be identified by a healthcare worker, by laboratory personnel, or by state/territory health authorities conducting routine surveillance or investigating reports of illness and from reportable disease notifications. When an outbreak is detected, the healthcare facility’s infection control management system should be notified and an outbreak control team formed relevant to the size and seriousness of the outbreak and the healthcare facility involved. There may also be a requirement to notify the state/territory public health unit.

The responsibility for investigation and the extent of investigations will vary according to the outbreak type and circumstances. It is important to investigate an outbreak immediately, as the availability and quality of microbiological evidence and epidemiological data diminishes rapidly with time between illness and investigation.

An outbreak management plan should be developed based on local policy and consultation between the infection control professional, healthcare workers, patients, facility management and state/territory health authorities as appropriate. Such a plan is multifactorial and its implementation is typically overseen by a person with designated responsibility for infection control, such as an infection control professional, clinical microbiologist or infectious diseases physician.

The outbreak response may differ according to the nature of disease, the virulence of the organism and the vulnerability of the patients concerned, however the principles that underlie an outbreak investigation are similar: identification of the aetiological agent; the route(s) of transmission; exposure factors and the population at risk.
Table B3.5 outlines the process of outbreak investigation and corresponding management. In practice many steps are taken more or less simultaneously, while the results of investigations and implementation of strategies to contain and control will vary with the availability and timeliness of information and seriousness of the outbreak. In primary care there may be a limited ability to investigate an outbreak, which will be generally conducted by public health authorities once they have been notified. All outbreaks, however minor, should be investigated promptly and thoroughly and the outcomes of the investigations documented.

**Table B3.5: Steps in an outbreak investigation**

<table>
<thead>
<tr>
<th>Steps</th>
<th>Suggested approach</th>
<th>Responsibilities (dependent on facility and type of outbreak)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1. Recognise outbreak and prepare to investigate</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Determine existence of the outbreak</td>
<td>• Establish background rate of disease&lt;br&gt;• Consider if observed number of cases is in excess of the usual number and cases are typical&lt;br&gt;• Examine surveillance data</td>
<td>• Healthcare workers&lt;br&gt;• Laboratory personnel</td>
</tr>
<tr>
<td>Determine if immediate control measures are needed (refer to B3.2.2)</td>
<td>• Reinforce standard precautions&lt;br&gt;• Apply appropriate transmission-based precautions</td>
<td>• Healthcare workers—as soon as outbreak is suspected</td>
</tr>
<tr>
<td>Notify and communicate</td>
<td>• Healthcare workers and ancillary staff in immediate area&lt;br&gt;• Infection control professional&lt;br&gt;• Executive&lt;br&gt;• Laboratory&lt;br&gt;• Public health unit (if notifiable disease or required pursuant to public health legislation)</td>
<td>• Healthcare workers—as soon as outbreak is suspected&lt;br&gt;• Laboratory personnel (e.g. routine screening can identify outbreak)—as soon as outbreak is suspected</td>
</tr>
<tr>
<td>Formation of an outbreak investigation/management team (OMT) – this will vary according to location/resources, made up of one or more people with designated responsibility</td>
<td>Membership may include but is not limited to: • Administrators (medical and nursing)&lt;br&gt;• Managers of implicated areas&lt;br&gt;• Infection control professional or designated person with infection control experience&lt;br&gt;• Clinical Microbiologist&lt;br&gt;• Infectious diseases physician/epidemiologist/statistician&lt;br&gt;• Lead investigator or ‘chair’ nominated&lt;br&gt;• Others as defined by circumstances</td>
<td>• Management—as soon as notified</td>
</tr>
<tr>
<td><strong>Step 2. Verify the diagnosis and confirm that an outbreak exists</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Confirm that there are more than expected number of cases meeting the surveillance case definition of the disease of interest in the period under review</td>
<td>• Confirm clinical diagnoses (symptoms and features of illness)&lt;br&gt;• Review laboratory data and request additional laboratory tests if necessary, e.g. molecular typing of organisms to confirm clonality</td>
<td>• Laboratory personnel to report results&lt;br&gt;• Clinicians to verify clinical diagnosis</td>
</tr>
<tr>
<td>Consider likely outbreak definition and whether criteria are met</td>
<td>– Are there more cases than expected compared to previous weeks / months?&lt;br&gt;– Review scientific literature&lt;br&gt;– Consider epidemiology of cases - are there two or more linked cases of the same illness?</td>
<td>• OMT representatives (clinical microbiologist, senior clinicians)</td>
</tr>
</tbody>
</table>
### Step 3. Establish case definition and find cases

Establish a set of standard criteria to decide whether or not a person has the disease of concern.

- **Case definition** should be based on:
  - Clinical information about the disease
  - Characteristics of the people who are affected
  - Information about the location
  - Specification of time period for the outbreak
- **Case definition** can be refined later after collection of primary data
- Cases can be classified as **'Confirmed'** (usually laboratory verification);
  **'Probable'** (usually has typical clinical features);
  **'Suspect'** (usually has fewer typical clinical features)

**Responsibilities** (dependent on facility and type of outbreak)

- OMT representatives (clinical microbiologist, senior clinicians)

<table>
<thead>
<tr>
<th>Steps</th>
<th>Suggested approach</th>
<th>Responsibilities</th>
</tr>
</thead>
</table>
| Step 3. Establish case definition and find cases | - Case definition should be based on:  
  - Clinical information about the disease  
  - Characteristics of the people who are affected  
  - Information about the location  
  - Specification of time period for the outbreak  
- Case definition can be refined later after collection of primary data  
- Cases can be classified as **'Confirmed'** (usually laboratory verification);  
  **'Probable'** (usually has typical clinical features);  
  **'Suspect'** (usually has fewer typical clinical features) | - OMT representatives (clinical microbiologist, senior clinicians) |
| Find cases | Gather critical information by:  
  - Interview  
  - Follow-up of disease notification  
  - Health alerts | - Healthcare workers  
- OMT representatives  
- Healthcare facility management |
| Identify and count cases | Collect the following types of information  
  - Identifying information  
  - Demographic information  
  - Clinical information  
  - Risk factor information (including environmental tests) | - OMT representative |
| Tabulate this information in a line list, that is updated as new cases appear | - Time – date of onset of illness  
  - Person – age, sex  
  - Place – where did the exposure occur?  
  - Other relevant information | - OMT representative |

### Step 4. Characterise outbreak by person, place, and time

Review descriptive epidemiology of all cases

- **Person:** sex, age, occupation, residence
- **Place:** information that provides information on possible source of agent and nature of exposure
- **Time:** date and time of onset; record relevant events in a timeline

Create epidemic curve to determine hypotheses

- **Number of cases on y-axis**
- **Time on x-axis**

**Responsibilities**

- OMT representative

### Step 5. Determine who is at risk

Identify groups at risk

- **Number of people ill**
- **Time and place of onset**
- **Personal characteristics**

**Responsibilities**

- OMT representative
### Initiate precautionary measures

- Use of standard precautions and appropriate transmission-based precautions
- Increase frequency and efficiency of environmental cleaning using appropriate products;
- Prophylactic treatment/immunisation
- Antibiotic restrictions
- Exclusion of cases from high risk activities
- Isolation and/or cohorting of patients
- Restricting movement of patients, staff and visitors
- Screening of patients with isolation of patients and cohorting of contacts;
- Provision of health information and advice

**Responsibilities (dependent on facility and type of outbreak)**

- Healthcare workers
- Infection control professional

### Steps

<table>
<thead>
<tr>
<th>Steps</th>
<th>Suggested approach</th>
<th>Responsibilities (dependent on facility and type of outbreak)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 6. Develop hypothesis – the ‘how’ and ‘why’</strong></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| Develop hypotheses from the factual information gathered to date on potential source, vector, pathogen, route of transmission | • Data collected by interview  
• Common links  
• Plausible exposures  
• Environmental test results where appropriate  
• Review literature | • OMT representative |
| **Step 7. Test hypothesis with established facts** | | |
| Perform epidemiologic study | • Cohort  
• Case-control | • OMT representative |
| Analyse the data | • Compare risk factors among ill (cases) vs. not ill (controls)  
• Attack rates  
• Relative risk | • OMT representative or outsourced to consultant with knowledge of statistical methods |
| **Step 8. Carry out further studies if necessary** | | |
| To support the hypothesis or if analytic studies do not confirm the hypothesis | • Further study to refine case definition  
• May involve testing of environmental samples, food samples or environmental screening in some situations (e.g. Legionella, Pseudomonas) | • OMT |
| **Step 9. Implement ongoing control / prevention measures** (This can be done at any time during the outbreak as deemed necessary). | | |
| Review measures initiated for immediate control (Step 1 and Step 5) | • Are infection control measures adequate to reduce risk of transmission? | • Healthcare workers  
• OMT  
• Healthcare facility management |
| Implement appropriate ongoing control measures and strategies to prevent further illness (see B.3.2.2) | • Restrict spread from the case  
• Interrupt chain of infection  
• Interrupt transmission or reduce exposure  
• Reduce susceptibility to infection  
• Assessment of policy, regulations, standards | • Healthcare workers  
• OMT  
• Healthcare facility management |
**Steps** | **Suggested approach** | **Responsibilities (dependent on facility and type of outbreak)**
---|---|---
Communicate and coordinate with all stakeholders | • Electronic flagging of medical records of contacts; • Reinforcement of infection control precautions to staff, patients and visitors | • Healthcare workers • OMT • Infection control professional
Make plans to evaluate their effectiveness | • Document type and time of implementation of infection control measures • Monitor factors contributing or affected by outbreak and any associated changes | • Healthcare workers • OMT • Infection control professional

**Step 10. Communicate findings**

Prepare written report that evaluates methods used for the control of the outbreak | • Include discussion of factors leading to outbreak, comprehensive timelines, summary of investigation and documented actions • Short and long term recommendations for prevention of similar outbreak • Disseminate to appropriate stakeholders including publication | • OMT • Healthcare facility management

---

**B3.2.2 Infection control strategies to control/contain an outbreak**

Good governance and administrative or managerial support are crucial to support outbreak management (see Section C1). The healthcare worker’s role in outbreak management will include:

- **reinforcement of standard precautions**, including rigorous adherence to the 5 moments for hand hygiene and environmental cleaning protocols and appropriate use of PPE
- **implementation of relevant transmission-based precautions**, including isolation and cohorting.

The specific precautions required for each infectious agent are listed in Section B5.2 (see page 165).

**Environmental cleaning**

Frequency and efficiency of environmental cleaning should be increased above the standard for the area to ensure any contaminants are removed (see Section B5.1 on page 161 for guidance on cleaning in high-risk situations). A targeted cleaning regime may be introduced and continued for the duration of the outbreak dependent on the mode of transmission of the infectious agent. Consideration should be given to whether the surrounding environment will need to be disinfected in addition to being cleaned.

**Patient isolation**

The isolation of infected patients—through allocation of single rooms or cohorting of patients—is important when managing an outbreak. Infected patients should be isolated using single rooms, cohorting and negative-pressure rooms if available and as advised by an infection control professional or person with designated responsibility for infection control. Standardised transmission-based precautions signage should identify the isolation room and include the necessary precautions to be adopted. The door should be kept closed for patients on airborne precautions.

**Single room**

Single-patient rooms are always indicated for patients placed on airborne precautions and are preferred for patients who require contact or droplet precautions. In the event of an outbreak, single-patient rooms are preferred for all modes of transmission.

When there is only a limited number of single-patient rooms, they should be prioritised for patients...
who have conditions that facilitate transmission of infectious material to other patients (e.g. draining wounds, stool incontinence, uncontained secretions) and for those who are at increased risk of acquisition and adverse outcomes resulting from infection (e.g. immunosuppression, open wounds, indwelling catheters, anticipated prolonged length of stay, total dependence on healthcare workers for activities of daily living).

**Cohorting**

Cohorting patients who are colonised or infected with the same strain confines their care to one area and prevents contact with other patients. Cohorts are created based on clinical diagnosis, microbiologic confirmation when available, epidemiology, and mode of transmission of the infectious agent. It is generally preferred not to place severely immunosuppressed patients in patient-care areas with other patients.

Cohorting allows more efficient use of staff. Cohorting has been used for managing outbreaks of MROs and pandemic influenza, and modelling studies provide additional support for cohorting patients to control outbreaks.

**Placement of large numbers of patients**

In the event of an outbreak or exposure involving large numbers of patients who require airborne precautions, an infection control professional should be consulted before patient placement. Appropriate measures may include:

- cohorting of patients in areas of the facility that are away from other patients
- using temporary portable solutions (e.g. exhaust fan) to create a negative pressure environment in the converted area of the facility.

**Restricting movement within the facility**

Restricting movement of patients during an outbreak reduces the risk of further transmission. If transfer within the facility or transport to another facility is necessary, advice should be sought from an infection control professional. If an infected or colonised patient must be moved the transport service and/or receiving area or facility should be notified of the nature of the patient's infection or colonisation.

It is important to:

- ensure that infected or colonised areas of the patient’s body are covered if relevant
- if the target infection is transmitted by the droplet or airborne route, ask the patient to wear a mask while being moved.

Contaminated PPE should be removed and disposed of and hand hygiene performed before the patient is moved. Clean PPE should be put on before the patient is handled at the destination.

**Exclusion policies**

Exclusion policies may also be implemented to restrict the spread of disease throughout a healthcare facility. This could include:

- excluding patients from participating in specific activities
- restricting or cancelling visiting hours for patients in outbreak areas
- excluding staff from work until well if they are implicated in the transmission of infection (e.g. food handlers).

In an outbreak of viral gastroenteritis, healthcare workers should not return to work until diarrhoea and vomiting have ceased for 2 days. It is extremely important that healthcare workers comply with appropriate hand hygiene methods and stringent infection control practices upon return to work, given that some studies have shown prolonged viral shedding.
Notifications and contact tracing

All healthcare facilities should have systems in place to ensure timely reporting of notifiable diseases to the relevant state/territory health department. As patients may present to a healthcare facility and be later confirmed to have a transmissible disease state/territory health authorities need to be notified to enable tracing of contacts of the infected patient in order to initiate appropriate counselling, quarantine and post-exposure prophylaxis. Healthcare facilities may need to identify staff on duty and other patients present who may have been exposed to the infectious patient and be at risk.

Communication

One of the important aspects of the outbreak management process is the written and oral communication of findings to the appropriate authorities, the appropriate health professionals and the public. This communication is based on the type and severity of the outbreak. During an outbreak it is important to provide education to the key stakeholders and clinicians about the organism, its mode of transmission and its behaviour in disease.

Within a healthcare facility, effective communication could consist of:

- appropriate signage to limit access to a room or a clinical unit
- electronic alerts on the medical record to manage cases and contacts
- emails and multimedia to target all stakeholders within the healthcare facility
- provision of education and written materials to visitors to inform them of the situation and the infection control measures with which they should comply.

Patient-care tip

Patients, their families, and visitors may experience concern or fear or may feel they are not being given enough information in an outbreak situation. Clearly explaining the process of outbreak management and the importance of infection control measures may assist them in understanding the situation and improve compliance with infection control directives.

B3.2.3 Applying transmission-based precautions during an outbreak

Successful outbreak management is based on a combination of transmission-based precautions. Specific interventions will be determined by the infection control professional, based on the mode of transmission of the infectious agent. These include:

- rigorous adherence to the 5 moments for hand hygiene (see Section B1.1.2);
- use of appropriate PPE (including gloves, apron or gowns, and surgical mask or P2 respirator);
- implementing patient-dedicated or single-use non-critical equipment (e.g. blood pressure cuff, stethoscope) and instruments and devices;
- following standard procedures for containment, cleaning and decontamination of spills; and
- increasing the frequency of environmental cleaning over the standard for that area, using appropriate products (see Section B5.1).
### B3.2.4 Risk-management case study

**Norovirus in a long-term care facility**

A patient from a self-contained unit within a long-term care facility is transferred to a hospital unit with dehydration resulting from diarrhoea. The infectious agent involved is identified as norovirus. The facility is contacted and advised to implement contact and droplet precautions, but these can only be implemented in the main facility and the following day the patient’s neighbour is also admitted with diarrhoea. When he and a third patient within the hospital unit are also confirmed as having norovirus, the three patients are isolated in single rooms with ensuites. Healthcare workers caring for the patients pay particular attention to hand hygiene and appropriate use of PPE. No further cases are identified. Investigation reveals low levels of hand hygiene among residents in the units. An education program is developed and provided to assist in preventing further infections.

<table>
<thead>
<tr>
<th>Eliminating risks</th>
<th>In this situation, it is not possible to eliminate risk, so it must be managed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifying risks</td>
<td>In this case, the risk has been identified as cross-transmission of norovirus by contact (faecal-oral) or droplet route.</td>
</tr>
<tr>
<td>Analysing risks</td>
<td>One source of the risk is the lack of appropriate hand hygiene practices by some residents. Each time there is social contact between these and other residents there is potential for cross-transmission. Depending upon hand hygiene practices among residents more broadly, there is potential for the infection to spread through the facility. There is also potential for residents with comorbidities who use the hospital to become reservoirs for transmission of the virus. Healthcare workers and visitors are also at risk of cross-contamination.</td>
</tr>
<tr>
<td>Evaluating risks</td>
<td>The balance of likelihood and consequences identify this as a ‘very high risk’ situation requiring immediate response.</td>
</tr>
<tr>
<td>Treating risks</td>
<td>Immediate measures may include increasing availability of soap and water as well as alcohol-based hand rub across the facility and raising residents’ awareness of the highly transmissible nature of norovirus infection, its modes of transmission and the particular need for hand hygiene practices. Frequency of environmental cleaning across the facility should also be increased. Longer-term measures could include providing education to residents and visitors on hand hygiene and other infection control measures. Education for healthcare workers could also be used to raise awareness of the high transmissibility of norovirus, and its capacity to spread very rapidly within units where there are poor or inadequate hygiene practices among residents and staff. Visitors should be requested not to enter the facility if they have any symptoms.</td>
</tr>
<tr>
<td>Monitoring</td>
<td>Changes in practice could be evaluated by surveying residents/patients on hand hygiene practice.</td>
</tr>
</tbody>
</table>
B3.3 Putting it into practice

Individual actions for reducing the risk

- Become familiar with local policy on the implementation of transmission-based precautions in the event of an outbreak
- If an outbreak is suspected or identified, implement core strategies for prevention and control and seek advice from an infection control professional or person with designated responsibility for this task regarding intensified strategies appropriate to the specific organism
- Practice hand hygiene assiduously and wear appropriate PPE when caring for patients who may be colonised or infected
- Become familiar with local policy on antibiotic stewardship.

Involving patients in their care

The following information may be provided to patients to assist them in understanding outbreak management.

- Hand hygiene is the most important part of preventing transmission of an infection—this applies to everyone including healthcare workers, patients, visitors and families
- If infected patients are transferred, they may be asked to wear a mask
- Infected patients should avoid unnecessary movement around other parts of the healthcare facility
- To minimise transmission of infection in hospitals, visitors should perform hand hygiene using alcohol-based hand rub before entering or exiting the patient-care area; they may also be asked to wear gloves and gowns while they are with the patient
- In hospitals, staff must respond quickly to an outbreak of an infection to contain the infection and stop it spreading any further. Actions may include testing patients to see who may be carrying the infection, placing patients in single rooms or with other patients who have the same infection, and limiting movement of people around the facility.

B3.5 References

B4 Applying standard and transmission-based precautions during procedures

**Summary**

Medical and dental procedures increase the risk of transmission of infectious agents between patients and healthcare workers.

- ‘Procedure’ includes any situation in which there is a potential for contact between the skin of the healthcare worker and the patient’s tissues, body cavities or organs, either directly or via surgical instruments or therapeutic devices.
- The more invasive the procedure, the greater the risk of transmission of infection. Before a procedure is undertaken, consideration should be given to whether there is a safer, less invasive alternative.
- The level of perceived infection risk depends on a range of factors including the site and complexity of the procedure and patient characteristics (e.g. age, underlying illness).
- Healthcare workers should be trained and competent in safe procedural techniques and participate in regular education sessions about minimising the infection risk of procedures. If there is any uncertainty, healthcare workers should contact the person with designated responsibility for infection control.

**Patient-care tip**

Patients and their carers should be offered clear, consistent information and advice through all stages of their care. This should include the risks of procedure-related infections, what is being done to reduce them and how they are managed.

This section outlines processes for risk identification and the application of standard and transmission-based precautions for certain procedures. It is not intended to provide guidance on performing procedures, but outlines the principles involved in the delivery of care that reduce the risk of transmission of infection during the insertion and maintenance of therapeutic devices and for surgery.

**Evidence supporting practice**

The advice in this section has been adapted from:

- the Institute for Healthcare Improvement (www.ihi.org)
- Pratt et al (2007) epic2: Guidelines for Preventing Healthcare-Associated Infections in NHS Hospitals (Sections B4.2.1 and 4.2.2)
- NICE (2003) Prevention of Healthcare-associated Infection in Primary and Community Care (Section B4.2.4)
- NICE (2008) Prevention and Treatment of Surgical Site Infection (Section 4.3).

---

16 These guidelines were selected based on analysis using the AGREE tool, which ensures that guidelines have been developed in a rigorous, transparent and robust manner. This process is discussed in detail in Appendix 2.
Further review of the literature conducted for these guidelines provided additional evidence on infection control measures required in the use of intravascular devices.17

B4.1 Taking a risk-management approach to procedures

All procedures involve some risk of infection. Minimising the infection risk associated with a procedure should be an integral part of considering the overall risks and benefits of that procedure to the patient. The aim should be to perform the procedure with the lowest level of perceived infection risk that will meet the treatment goals for that patient. When performing the procedure, associated infection risks should be identified and minimised.

In developing local policies for a healthcare facility, it is useful to refer to guidelines developed to inform practice in performing specialised procedures.

B4.1.1 Classifying procedures

Procedures can be classified according to the level of perceived risk, by applying the principles of Spaulding's criteria for assessing the risk of medical instruments and equipment according to their intended use (see Section B1.5).

<table>
<thead>
<tr>
<th>Level of risk</th>
<th>Criteria</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>High risk</strong></td>
<td>Any surgical entry into tissue, body cavities or organs, or repair of traumatic injury.</td>

</tr>
<tr>
<td>(non-critical site)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

B4.1.2 Appropriate use of devices

Appropriate use of devices is integral to reducing the risk of procedures. Single-use or single-patient items should be used wherever practical, and items designed for single use must not be used for multiple patients. Healthcare workers should be aware of situations where cross-contamination may occur during routine procedures.

Healthcare workers must adhere to infection control principles, including safe injection practices and aseptic technique for the preparation and administration of parenteral medications.

17 The report of this review is available from the NHMRC upon request.
Single-dose vials

Medications or solutions that come into contact with normally sterile tissue should be sterile. The most effective way to avoid cross-infection via injection of medication is through the use of single-dose vials or ampoules and single-use sterile injecting equipment. Single-dose vials or ampoules, or prefilled syringes, should be used wherever these are available. These include the use of a sterile, single-use needle and syringe for each injection given, and adherence to practices that prevent contamination of injection equipment and medication.

Multi-dose vials

The Australian Drug Evaluation Committee (ADEC) has advised that injectable products packaged in multi-dose vials should not be used except where products such as insulin are intended solely for the exclusive use of an individual patient (ADEC 2005). In these particular cases, specific protocols should be in place to ensure the products are used for those individuals only, and there is adherence to practices that prevent contamination of injection equipment and medication.

Currently some injectable products (e.g. Bacillus Calmette-Guérin [BCG] and botulinum toxin) are only available in multi-dose vials. When single-dose vials or ampoules are not available, there is a high risk of cross-contamination if injectable products are used on multiple patients. Steps should be taken to ensure these become available in single dose vials, however the risk of infectious disease transmission may be mitigated by (Siegel et al 2007):

- compliance with manufacturer’s recommendations (adhere to instructions for refrigeration, storage, use within a specified time, expiry date)
- establishing a separate area designated for the placement of these medications away from any work area
- having only the current patient’s medication in the immediate working environment
- using a sterile needle and syringe to draw up the required dose from the vial or ampoule on every occasion
- using a sterile needle to draw up all the contents of the container into individual syringes before administering to patients
- discarding any open ampoule(s) at the end of each procedure
- discarding product if sterility is compromised or questionable.

The use of multi-dose vials has been associated with the transmission of infectious diseases including HIV (Katzenstein et al 1999), hepatitis B (Hutin et al 1999; Dumpis et al 2003; Samandari et al 2005), hepatitis C (Widell et al 1999; Massari et al 2001; Trasancos et al 2001; Kokubo et al 2002; Silini et al 2002; Dumpis et al 2003; Germain et al 2005; Verbaan et al 2008), Staphylococcus aureus (Kellaway et al 1928), and Streptococcus pyogenes (Stetler et al 1985; Olson et al 1999). International agencies such as the CDC and WHO recommend that single-dose vials be used for parenteral additives or medications whenever possible, especially when medications will be administered to multiple patients (Hutin et al 2003; Siegel et al 2007).

There may be some exceptional circumstances where for short periods (e.g. a few months) multi-dose vials may be the only way to deliver vaccines or drugs to a large proportion of the population in a timely fashion. An example would be when a health emergency is declared because of an infection that has a high associated mortality and rapid spread (e.g. smallpox outbreak) and when there may be a delay in single-dose vaccines or drugs becoming available for a period of time.
Table B4.2: Summary of processes for appropriate use of devices

<table>
<thead>
<tr>
<th>Device Type</th>
<th>Processes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Injection equipment</td>
<td>• Avoid contamination of the needle</td>
</tr>
</tbody>
</table>
| Single-use items | • Do not use the same needle, cannula or syringe for more than one patient nor to access a medication or solution that might be used for a subsequent patient  
• Do not administer medications from a single syringe to multiple patients, even if the needle or cannula on the syringe is changed. |
| Single-patient items | • Use single-patient items for one patient only and dispose of them appropriately. |
| Single-use medications | • Only use single-dose vials when administering drugs, therapeutic agents and vaccines to multiple patients  
• Do not administer medications from single-dose vials or ampoules to multiple patients or combine leftover contents for later use |
| Multi-dose vials | • Multi dose vials should not be used except where they are intended solely for the exclusive use of an individual patient (e.g. insulin) |
| Fluid infusion and administration sets (i.e. intravenous bags, tubing and connectors) | • Use for one patient only and dispose of appropriately after use  
• Do not use bags or bottles of intravenous solution as a common source of supply for multiple patients  
• Consider syringes or needles/cannulae as contaminated once they have been used to enter or connect to a patient’s intravenous infusion bag or administration set  
• Use closed intravenous delivery devices as standard practice  
• Use premixed intravenous bags of medication wherever possible, in order to reduce the risk of contamination or infection during mixing, dilution or preparation  
• Avoid disconnection of administration sets if possible to minimise the potential of contamination of IV lines  
• Should be changed on a regular basis, depending on their use (see Section B4.2.2) |

B4.1.3 The care bundle approach

The Institute for Healthcare Improvement (IHI) in the US developed a structured ‘care bundle’ approach to help healthcare workers consistently deliver the safest possible care for patients undergoing treatments with inherent risks. A bundle is a set of evidence-based practices that, when performed collectively and reliably, improve patient outcomes.

Many bundle elements are well-established practices, combined in a structured protocol that is agreed upon and is the responsibility of the whole clinical team. Bundle characteristics include the following.

• A bundle is a cohesive unit of steps that must all be completed to succeed.
• The elements are all based on randomised controlled trial evidence.
• The elements involve all-or-nothing measurement, making implementation clear-cut.
• Bundle elements occur at a specific time and in a specific place (e.g. during morning rounds every day).

Examples of care bundles are given in each section of this chapter. These can be used to monitor, assess and improve performance as well as to increase consistency of care.

Existing care bundles can be used as a tool and be developed by each facility to meet its needs. For more information, refer to the IHI website at www.ihi.org.
B4.2 Therapeutic devices

Therapeutic devices include catheters inserted for drainage (e.g. urinary catheter), for intravascular access (e.g. central venous line), for mechanical ventilation (e.g. intubation) and for feeding (e.g. enteral feeding tube).

Indwelling devices provide a route for infectious agents to enter the body. Aseptic insertion and careful maintenance of devices is critical to reducing infection risk.

Therapeutic medical devices are a common source of HAIs in intensive care units. Pneumonia, urinary tract infections and bloodstream infection account for around 70% of intensive care unit HAIs, and most of these are associated with invasive devices (Cruickshank & Ferguson 2008).

Table B4.3: Key concepts in minimising the risk of infection related to the use of invasive devices

- Consider the infection risk during decision-making about whether or not to perform the procedure, ensuring that a therapeutic device is absolutely necessary for the patient
- Ensure you are adequately trained and competent in the skills required for safe insertion and maintenance of the device
- Choose the most appropriate device for the patient
- Minimise the period of time a device remains in a patient
- Use processes identified as those that minimise the risk of infection (see summary tables in this section)
- Regularly monitor patients for any signs and symptoms of infection
- Provide patient education on the infection risk associated with the insertion of devices and the importance of proper maintenance

Information on use of aseptic non-touch technique (ANTT) for specific procedures (including therapeutic devices) can be found in Sections B1.7 and B5.4.

B4.2.1 Indwelling urinary devices

An indwelling urinary catheter is a flexible tubular instrument passed into the bladder either through the urethra or though the abdominal wall above the symphysis pubis. They are used to empty the contents of the bladder in patients with acute urine retention or peri-operatively, and for urinary measurements in critically ill patients.

What are the risks?

Bacterial infections associated with urinary catheterisation gain access to the urinary tract either through:

- **extraluminal contamination**—this can occur if there is a break in aseptic technique during insertion of the catheter or servicing the drainage system, from the healthcare worker’s hands or from the patient’s own colonic or perineal flora
- **intraluminal contamination**—this can occur through reflux of bacteria from a contaminated urine drainage bag.

Catheterising patients places them at significant risk of acquiring a urinary tract infection. The risk of infection is associated with the method and duration of catheterisation, the quality of catheter care and host susceptibility. The longer a urinary catheter is in place, the greater the risk of infection.

---

Between 15 and 25% of patients in hospital may receive short-term indwelling urinary catheters, and about 5% of residents in long-term care facilities (O’Grady et al 2002; draft 2009). Around 20% of HAIs are urinary tract infections, and a large proportion of these are catheter-associated urinary tract infections (CAUTIs) (Smyth et al 2008). Up to 97% of urinary tract infections in intensive care units have been associated with indwelling catheters (Cruickshank & Ferguson 2008).

Minimising the risk from indwelling urinary devices

Limiting catheter use and minimising duration are primary strategies in reducing the risk of CAUTI. Healthcare facilities should have documented policies regarding insertion, maintenance and surveillance of indwelling urinary catheters. Facilities should clearly outline the indications for catheter insertion.

Healthcare workers performing catheterisation should be trained and competent in the technique and familiar with policies and procedures for insertion, maintenance and changing regimes of indwelling urinary devices.

Insertion

• The need for insertion of an indwelling urinary device should be reviewed before the procedure is performed.

• Principles of good practice, clinical guidance and expert opinion, together with findings from a systematic review agree that urinary catheters should be inserted using sterilised equipment (including a sterile drape) and an aseptic technique, using the smallest bore catheter possible that will not be associated with leakage. Staff performing the procedure must be trained and competent in the technique.

• Expert opinion indicates that there is no advantage in using antiseptic preparations over sterile saline for cleansing the urethral meatus prior to catheter insertion. The use of lubricant or anaesthetic gel minimises urethral trauma and discomfort.

Maintaining the system

• Maintaining an aseptic, continuously closed urinary drainage system is central to the prevention of CAUTI. Breaches in the closed system, such as unnecessary emptying of the urinary drainage bag or taking a urine sample, increase the risk of catheter-related infection. Reflux of urine from the drainage bag is also associated with infection.

• Studies investigating the addition of disinfectants and antimicrobials to drainage bags as a way of preventing CAUTI show no reduction in the incidence of bacteriuria following the addition of hydrogen peroxide or chlorhexidine.

• The device should be removed immediately it is no longer needed.

Patient care

• No reduction in bacteriuria has been demonstrated when antiseptic/antimicrobial agents are used for meatal care compared with routine bathing or showering. Expert opinion and a systematic review support the view that vigorous meatal cleansing is not necessary and may increase the risk of infection and that daily routine bathing or showering is all that is needed to maintain meatal hygiene.

• Evidence indicates that bladder irrigation, instillation and washout may have local toxic effects and contribute to the development of resistant microorganisms. However, continuous or intermittent bladder irrigation may be indicated during urological surgery or to manage catheter obstruction.
**Documentation and surveillance**

- The literature emphasises the importance of documenting all procedures involving the catheter or drainage system in the patient’s records and providing patients with adequate information in relation to the need for catheterisation and details of the insertion, maintenance and removal of their catheter.

- Surveillance relating to indwelling catheters is recommended in the literature and can include monitoring compliance with indications for insertion and documentation.

**Patient-care tip**

Given the risk of urinary tract infection associated with urinary catheterisation, it is important that patients and relatives understand about infection prevention, are aware of the signs and symptoms of urinary tract infection and know how to access expert help if difficulties arise.

**Table B4.4: Summary of processes for urethral catheter insertion and maintenance**

<table>
<thead>
<tr>
<th>Insertion</th>
<th>Maintenance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ensure documented facility policy on urethral catheter insertion is being followed and that staff members performing the procedure are trained in the specific technique.</td>
<td>Use an aseptic closed system and avoid breaches to this system (e.g. unnecessary emptying of the urinary drainage bag)</td>
</tr>
<tr>
<td>Use sterile equipment (including a sterile drape) and aseptic technique when inserting urinary catheters and connecting to the sterile system</td>
<td>Before manipulation, perform hand hygiene and put on non-sterile gloves</td>
</tr>
<tr>
<td>Clean the urethral meatus with sterile normal saline before insertion of the catheter</td>
<td>Position drainage bag to prevent back-flow of urine or contact of bag with the floor</td>
</tr>
<tr>
<td>Use an appropriate sterile, single-use lubricant or anaesthetic gel</td>
<td>Do not add antiseptic or antimicrobial solutions into drainage bags</td>
</tr>
<tr>
<td>Properly secure catheter after insertion to prevent movement and urethral traction</td>
<td>Empty the drainage bag frequently enough to maintain urine flow and prevent reflux</td>
</tr>
</tbody>
</table>

- Use a separate urine collection container for each patient, avoiding contact between the drainage bag and container. Following use, the container should be discarded if single use, or cleaned and sterilised if reusable.

- Change drainage bags only when necessary (i.e. according to either manufacturers’ recommendations of the patient’s clinical needs).

- Clamping is unnecessary.

- Daily meatal hygiene can be maintained through routine bathing or showering.

- Avoid use of bladder irrigation, instillation or washouts as routine measures to prevent catheter-associated infection.

- Document all procedures involving the catheter or drainage system.
Table B4.5: CAUTI maintenance bundle

An example of a bundle procedure for maintenance of urinary catheters is to:

- Perform a daily review of the need for the urinary catheter
- Check the catheter has been continuously connected to the drainage system
- Ensure patients are aware of their role in preventing urinary tract infection, or if the patient is unable to be made aware, perform routine daily meatal hygiene
- Empty urinary drainage bags frequently enough to maintain urine flow and prevent reflux. Use a separate urine collection container for each patient, avoiding contact between the drainage bag and container
- Perform hand hygiene and put on gloves and apron before each catheter care procedure; on procedure completion, remove gloves and apron and perform hand hygiene again

These practices can be measured and used to monitor performance by the clinical team.

B4.2.2 Intravascular access devices

Indwelling intravascular access devices (catheters) provide a route for:
- administering fluids, blood products, nutrients and intravenous medications
- monitoring haemodynamic function
- maintaining emergency vascular access
- obtaining blood specimens.

Intravascular devices (IVDs) are catheters that are usually inserted into peripheral veins (e.g. small veins in the arms). Peripheral arterial devices are also used for some patients.

Central venous catheters are inserted into larger veins within the chest and abdomen. They generally remain in place for longer than peripheral vein catheters.

Some central venous catheters are inserted through a peripheral vein site (peripherally inserted central catheters [PICC or PIC lines]). They can be used for a prolonged period of time (e.g. for long chemotherapy regimens, extended antibiotic therapy, or total parenteral nutrition).

IVD insertion is the most commonly performed invasive healthcare procedure with approximately 14 million IVDs used in Australia each year (Collignon 1994; ABS 2008).

What are the risks?

IVDs provide potential routes for infectious agents to cause local infection or to enter the bloodstream. As a result, despite their important role in diagnostic and therapeutic care, IVDs are a potential source of HAIs, the most severe form being bloodstream infections (BSI) associated with the insertion and maintenance of central venous access devices. There are about 5,000 cases of IVD-related BSI a year in Australia (Collignon 1994; ABS 2008). IVD-related BSIs are associated with significant mortality, worsen the severity of the patient’s underlying ill health, prolong the period of hospitalisation and increase the cost of care.

There is risk of infection when the device is inserted and while it remains in situ. The risks inherent in insertion of IVDs include bypassing the skin, which is such an important barrier against microorganisms gaining entry to sterile sites such as the bloodstream, and leaving a foreign body in the patient for several days or longer which is likely to become colonised by microorganisms.

1. Skin organisms: Colonisation of the external surfaces of the IVD by microorganisms from the patient’s skin around the insertion site. This can occur through contamination of the catheter tip at the time of insertion or migration of skin organisms at the insertion site into the cutaneous catheter tract after insertion.

2. Contamination of the catheter hub with distal spread of the organisms down the intraluminal surface. This is largely thought to occur during handling of the connections at catheter junctions.

3. Occasionally, the catheter might become haematogenously seeded from another focus of infection.

4. Contamination of the fluid infusate occurs on rare occasions.

**Source:** Illustration used with permission from Professor Dennis Maki.

**Table B4.6: Risk factors for IVD-related BSI**

- Prolonged hospitalisation before the IVD is inserted
- Prolonged placement of the device
- Heavy microbial colonisation of the insertion site that contaminate the catheter during insertion and migrate along the cutaneous catheter track
- Heavy microbial colonisation of the cannula/catheter hub, usually secondary to contamination from healthcare workers’ hands during care interventions such as injections
- Antibiotic use during catheterisation.

The microorganisms that colonise catheter hubs and the skin adjacent to the insertion site are the source of most IVD-related BSI. Coagulase-negative staphylococci, particularly *Staphylococcus epidermidis*, are the most frequently implicated microorganisms. Other microorganisms commonly involved include *Staphylococcus aureus*, *Candida* species and enterococci.

Prolonged duration of peripheral IV catheters greatly increases the risk of infection—while only 1–2% of peripheral catheters remain in place for longer than 2 days, these are associated with 90% of IVD-related BSIs (Collignon P, unpublished study).
**Minimising the risk from intravascular access devices**

To minimise the risk to patients, IVDs should only be used when absolutely necessary. They must be removed as soon as they are no longer needed or alternative means are available to deliver appropriate care (e.g. oral drugs instead of IV delivery). Prevention of catheter-related BSI requires a set of infection control measures (see care bundles box below).

**Decision-making about IVDs**

Decision-making about IVDs should involve the consideration of:

- whether oral administration is possible
- which device poses the lowest risk to the patient
- the reduced risk of sepsis associated with permanent access devices (e.g. fistula) if long-term administration is required (e.g. for haemodialysis)
- the importance of removing the IVD when it is no longer needed or a safer alternative can be used.

If a central venous access catheter is necessary, it must be inserted under maximal barrier precautions (i.e. similar to surgical procedures). The femoral site of insertion should be avoided (Hamilton & Foxcraft 2008).

**Table B4.7: Central venous catheter decision tree for adults**

- Assess the physical status and vascular access history of the patient
- Base a decision on the type and duration of therapy required
- Carefully consider the need for central v peripheral vascular access
- Do not lose sight of the patient as the focus for your decision
- Ensure clear documentation of all key events in the clinical record

Source: The Canberra Hospital.

**Evidence supporting practice**

**Site preparation**

- Alcohols are the most effective and most rapid-acting skin antiseptics. Alcohol-based preparations that have 70% isopropyl alcohol v/v and at least 0.5% chlorhexidine are recommended for procedures penetrating skin (including subcutaneous infusions). Typically available solutions range from 0.5% to 4% and there is strong evidence (Grade A) that skin preparations with at least 0.5% chlorhexidine-gluconate solution reduce intravascular device colonisation.

**Insertion of IVDs**

- There is Grade B evidence that maximum barrier precautions (inserter wears mask, cap, sterile gown, sterile gloves, uses large sterile drape; assistant wears cap and mask) reduce immediate post-insertion skin colonisation in short-term central venous devices.
- Maximum barrier precautions are not necessary for insertion of short peripheral venous or arterial devices; device colonisation or IVD-related BSI was not reduced compared to when standard good practice care was used (inserter wears sterile gloves and uses sterile equipment).

---

20 Based also on evidence identified through Richard C, Ray-Barruel G (2009). Systematic literature review of infection control literature relating to intravascular devices conducted to inform the development of these guidelines.
**Maintenance**

- The safe maintenance of an IVD includes good practice in caring for the patient’s catheter hub and connection port to avoid contamination by staff hands, the use of an appropriate site dressing regimen, and using flush solutions to maintain the patency of the line.

- For patients who require long-term venous access (e.g. renal dialysis), permanent access devices (e.g. fistulas) reduce the risk of infection compared to other forms of IV access.

**Choice of dressings**

- There is strong evidence (Grade B) that the use of chlorhexidine-impregnated (CHG) sponges at the catheter insertion site significantly reduces IVD-related bloodstream infection and device colonisation rates compared to other types of dressings for peripheral arterial devices, short-term and long-term central venous devices. The safety of these sponges has not been established in low birth-weight neonates who may be at risk of skin or systemic toxicity.

- There is insufficient evidence to determine a significant difference in the use of sterile gauze over other dressings (tape, transparent polyurethane, or highly moisture permeable transparent dressings) to reduce phlebitis incidence in peripheral IVDs and tunnelled central venous catheters (used for haemodialysis and oncology); or in preventing infectious complications in short and long-term central venous devices (including those used for haemodialysis).

- Patient preference, clinician preference and costs are currently acceptable factors when choosing between sterile gauze and transparent polyurethane dressings.

- There is Grade B evidence that the use of an antimicrobial or antibiotic ointment (calcium mupirocin, or Polysporin) on long-term tunnelled central venous devices used for haemodialysis access, significantly reduces IVD-associated BSIs and exit site infections.

- Povidone iodine antiseptic ointment or bacitracin/neomycin/polymyxin B ointment should only be used at the hemodialysis catheter exit site after catheter insertion and at the end of each dialysis session if this ointment does not interact with the material of the hemodialysis catheter (as per manufacturer’s recommendations)(O’Grady et al 2002).

**Changing dressings**

- The evidence (Grade C) supports daily examination of short-term vascular catheter dressings to assess whether they require changing. Dressing change is indicated where the dressing is loose or soiled.

- There is strong evidence that scheduled seven-day replacement of transparent dressings for short-term central venous and peripheral arterial devices (with or without CHG sponges) is equally as effective in preventing device colonisation and IVD-related BSI as scheduled three-day replacement.

- There is some evidence that eight-day replacement of transparent dressings for tunnelled central venous devices significantly reduces skin toxicity, and does not change IVD-related BSI rates, compared with four-day replacement.

- Evidence regarding paediatric central venous device dressings (Grade C) suggests that these should be changed at least every seven days.

**Device replacement**

- In adults, most studies use phlebitis (which may have a chemical or traumatic basis) as an endpoint and find little or no benefits for routinely changing short peripheral vein catheters Evidence suggests that bacteraemia is disproportionately associated with catheters in place for more than 2 days. Removing a catheter eliminates the risk for associated sepsis.

- There is some evidence that routine replacement of short-term central venous devices compared with replacement on clinical indication has no effect on IVD-related BSI rates per adult patient.
Replacement of administration sets

- There is strong evidence (Grade B) that administration sets that do not contain lipids, blood or blood products may be left in place for intervals of up to 4 days.

Patient-care tip

Before discharge from hospital, patients and their carers should be provided with education, supported by written instructions, on the management and care of an indwelling device, including the prevention of infection.

Table B4.8: Summary of processes for insertion, maintenance and replacement of intravascular access devices

| Site preparation | In selecting the best insertion site, consider patient-specific factors and the relative risk of mechanical complications
| Allow sufficient contact time for site preparation—clean a site large enough for insertion before applying antisepsis and allow to dry completely
| Before device insertion, decontaminate the site using a single-use application of alcohol-based chlorhexidine gluconate solution (0.5% chlorhexidine gluconate in 70% isopropyl alcohol)
| If insertion through or close to mucous membranes is necessary, use aqueous solution supplemented with 2% chlorhexidine
| For patients with a history of chlorhexidine sensitivity, use 5% alcohol-based povidone-iodine solution or 10% aqueous povidone-iodine if insertion is through or close to mucous membranes

| Insertion | Use maximum barrier precautions for insertion of all central venous catheters, including PICC lines
| Use aseptic non-touch technique for insertion of peripheral venous, arterial or subcutaneous devices (see Section B5.4.1)
| If an intravascular device is inserted in an emergency, remove within 24 hours and insert a new device under appropriate conditions
| When PICC insertion is done at the bedside (i.e. in the patient’s room), establish a suitable aseptic field and maintain this throughout the procedure

| Maintenance | Use hand antisepsis and aseptic non-touch technique for catheter site care and for accessing the system
| Use CHG sponge dressings for peripheral arterial devices, short-term and long-term central venous devices
| Use sterile gauze or sterile, transparent, semi-permeable dressings to cover the catheter site
| If the patient is diaphoretic, or if the site is bleeding or oozing, use a gauze dressing
| For long-term tunnelled central venous devices used for haemodialysis, use an antimicrobial or antibiotic ointment at the exit site after catheter insertion and at the end of each dialysis session unless the ointment interacts with the material of the catheter

| Changing dressings | Examine short-term vascular catheter dressings daily and change if soiled or loosened
| Examine dressings for short-term central venous and peripheral arterial devices daily and replace: when soiled or loose; if the patient’s clinical presentation indicates a BSI; and after seven days for paediatric patients
| Monitor dressings for tunnelled central venous devices and replace when soiled or loose, or after 8 days

| Device replacement | Assess all devices daily and remove if no longer needed or if complications occur
| Routinely replace peripheral intravenous devices every 2 to 3 days or sooner if clinically indicated
| Do not routinely replace central venous catheters and PICC lines in neonates, children or adults
| Do not routinely replace pulmonary artery catheters in neonates and children
| In paediatrics, replace all catheters once IV therapy is complete unless there are indications of a BSI

| Replacement of administration sets | Leave administration sets that do not contain lipids, blood or blood products in place for intervals of up to 4 days
| Change administration sets used for intermittent infusion of blood, blood products or lipid emulsions (including 3-1 parenteral nutrition solutions) when the infusion is complete or at least every 24 hours
| Change administration sets used to infuse propofol at a minimum of 12 hours or as per manufacturer’s guidelines

![Image of PPE and maximal barrier precautions for IVD insertion]

**IVD care bundles**

There are numerous care bundles in use on the management of central and peripheral vascular devices. Information on bundles and their implementation is discussed in Section B4.1.3.

Before implementing a care bundle it is important to identify current practice in the particular area. Gaps in service provision need to be identified, analysed and systematically addressed through the implementation of the bundle.

Examples available bundles include:
- Health Protection Scotland [http://www.hps.scot.nhs.uk/haic/ic/bundles.aspx](http://www.hps.scot.nhs.uk/haic/ic/bundles.aspx)

### B4.2.3 Ventilation

Certain patients require mechanical ventilatory support by endotracheal tube or tracheostomy. Common medical indications include acute lung injury, chronic obstructive lung disease and acute respiratory acidosis.

**What are the risks?**

Ventilator-associated pneumonia (VAP) is a type of hospital-acquired pneumonia that can occur in up to 25% of all people who require mechanical ventilation. VAP is a common cause of morbidity and mortality with crude death rates of 5 to 65% as well as increased healthcare costs. VAP can develop at any time during ventilation, but occurs more often in the first few days after intubation, because the intubation process itself contributes to the development of VAP.

VAP primarily occurs because microorganisms colonise the endotracheal or tracheostomy tube and are embolised into the lungs, often in patients who may have underlying lung or immune problems. Bacteria may enter the lungs with procedures such as bronchoscopy.

**Minimising the risks of VAP**

Many practices have been demonstrated to reduce the incidence of VAP and its associated burden of illness. The first consideration should always be whether intubation is necessary.

---

Physical strategies

- Oral endotracheal intubation is associated with a trend toward a reduction in VAP compared to nasotracheal intubation and with a decreased incidence of sinusitis (the incidence of VAP is lower in patients who do not develop sinusitis). Reintubation should be avoided if possible.

- The frequency of ventilator circuit changes does not influence the incidence of VAP. Circuits should be changed if they become soiled or damaged. New ventilator circuit tubing should be provided for each patient.

- There is no difference in the incidence of VAP between patients whose airways are humidified using a heat and moisture exchanger and those whose airways are humidified using a heated humidifier. The decision should be made for each patient, with the aim to ensure adequate moisture output to minimise the risk of airway obstruction.

- Less frequent heat and moisture exchanger changes may be associated with a slightly decreased incidence of VAP. Reducing the frequency of humidifier changes might be considered as a cost-reduction measure.

- The type of suctioning system has no effect on the incidence of VAP. Safety considerations (patient and healthcare worker exposure to aerosolised secretions) favour the use of closed systems. The number of disconnections of suction equipment should be minimised to reduce the risk of exposure to staff to potentially infected secretions.

- Scheduled daily changes and unscheduled changes of closed systems have no effect on VAP.

- Subglottic secretion drainage is associated with a decreased incidence of VAP. To increase their utility and cost-effectiveness, these tubes should only be placed in patients expected to require prolonged mechanical ventilation.

Positional strategies

- The use of rotating beds is associated with a decreased incidence of VAP.

- Semi-recumbent positioning may be associated with a decreased incidence of VAP. However, semi-recumbent positioning may be unsafe for some patients.

Pharmacologic strategies

- The use of the oral antiseptic chlorhexidine may decrease the incidence of VAP. Safety, feasibility, and cost considerations for this intervention are all very favorable.

- The use of the oral antiseptic povidone-iodine decreases the incidence of VAP in patients with severe head injuries. Safety, feasibility, and cost considerations for this intervention are all very favorable. There are insufficient data to make a recommendation in critically ill patients other than those who have severe head injury.

Table B4.9: Summary of strategies for preventing VAP

VAP care bundles

There are numerous care bundles in use on the management and prevention of VAP. Information on bundles and their implementation is discussed in Section B4.1.3. Before implementing a care bundle it is important to identify current practice in the particular area. Gaps in service provision need to be identified, analysed and systematically addressed through the implementation of the bundle.

Examples of available bundles include:
- Scottish Infection Care Society Audit Group VAP Prevention Bundle http://www.sicsag.scot.nhs.uk/SubGroup/VAP_Prevention_Bundle_Bedside_Aide_Memoire.pdf
- IHI Ventilator Bundle http://www.ihi.org/IHI/Topics/CriticalCare/IntensiveCare/Changes/ImplementtheVentilatorBundle.htm

B4.2.4 Enteral feeding tubes

Enteral feeding is usually prescribed for patients in hospital requiring artificial nutrition support for 7–10 days and long-term feeding / home enteral tube feeding may be considered for patients needing artificial nutrition support for more than 30 days.

What are the risks?

Contamination of feeds is a key concern in both the hospital and community setting, with contamination largely occurring during the preparation or administration of feeds and being linked to serious clinical infection.

Minimising the risks of enteral feeding tubes

Most evidence concerning enteral feeding relates to gastrostomy or percutaneous endoscopic gastrostomies (PEG feeds). However, the principles outlined here are also applicable to nasogastric and jejunostomy feeding.

- Standard principles stress the importance of hand hygiene and expert opinion stresses the need to prepare the work surface and, where necessary, the equipment for reconstituting or diluting the feed. Even closed systems can become contaminated if hand hygiene is not adequate.
- Closed systems (i.e. sterilised prefilled ready-to-use feeds that do not expose feed to the air during assembly) as available from all major manufacturers, have lower contamination rates than open systems. The design of the system is also important in order to minimise handling.
- Bacterial contamination has been associated with the re-use of feed bags and administration sets. As evidence suggests re-use is not advisable, the administration system should be considered single use only and discarded after each session.
- There is some evidence related to infection immediately after insertion of the first tube, but no evidence relating to infections in a healed stoma.
- To help minimise the potential risk of microbial colonisation of the internal and external surfaces of enteral feeding tubes, expert opinion suggests that the tube should be flushed with fresh tap water before and after each change of feed, aspiration or medication administration. Cooled boiled water or freshly opened sterilised water should be used for flushing enteral feeding tubes in immunocompetent patients.

Patient-care tip

Patients and carers should be educated in techniques of hand hygiene, enteral feeding and the management of the administration system before being discharged from hospital.

22 Unless otherwise specified, this section is drawn from NICE (2005) Prevention of Healthcare-associated Infection in Primary and Community Care.

B4.3 Surgical procedures

The discussion in this section applies to all surgical procedures regardless of setting. While there is less evidence for surgical procedures in office-based practice than in hospitals, the same principles apply.

B4.3.1 What are the risks?

The microorganisms that cause surgical-site infections are usually derived from patients (endogenous infection), being present on their skin or from a surgical opening in the body. Exogenous infection occurs when microorganisms from instruments or the operating environment contaminate the site at operation, when microorganisms from the environment contaminate a traumatic wound, or when microorganisms gain access to the wound after surgery, before the skin has sealed.

The risk of surgery-related infection is increased by factors that:

• increase the risk of endogenous contamination (e.g. procedures that involve parts of the body with a high concentration of normal flora such as the bowel)
• increase the risk of exogenous contamination (e.g. prolonged operations that increase the length of time that tissues are exposed)
• diminish the efficacy of the general immune response (e.g. diabetes, malnutrition, or immunosuppressive therapy with radiotherapy, chemotherapy or steroids) or local immune response (e.g. foreign bodies, damaged tissue or formation of a haematoma).

23 Unless otherwise specified, this section is drawn from NICE (2008) Prevention and Treatment of Surgical Site Infection.
B4.3.2 Minimising the risk of surgical procedures

Practices to prevent surgical-site infections are aimed at minimising the number of microorganisms introduced into the operative site, for example by:

- removing microorganisms that normally colonise the skin
- preventing the multiplication of microorganisms at the operative site, for example by using prophylactic antimicrobial therapy
- enhancing the patient’s defences against infection, for example by minimising tissue damage and maintaining normothermia
- preventing access of microorganisms into the incision postoperatively by use of a wound dressings.

This section gives general guidance on preventing surgical infection. More detailed information can be found in the NICE surgical-site infection guidelines (NICE 2008).

Patient-care tip

Patients and carers require clear, consistent information and advice throughout all stages of their care, including:

- the risks of surgical-site infections, what is being done to reduce them and how they are managed
- how to care for their wound after discharge
- how to recognise a surgical-site infection and who to contact if they are concerned.

An integrated care pathway helps to communicate this information to both patients and all those involved in their care after discharge.

Patients should always be informed if they have been given antibiotics.

Hand hygiene for surgery

Surgical hand preparation should reduce the release of skin bacteria from the hands of the surgical team for the duration of the procedure in case of an unnoticed puncture of the surgical glove that releases bacteria to the open wound. Surgical hand preparation must eliminate the transient and reduce the resident flora. There are special surgical scrub formulations available for use, although any product used within Australia should preferably be approved by the TGA. Current WHO guidelines recommend the use of an alcohol-based formulation for preoperative surgical hand preparation given its superior antimicrobial efficacy compared to other methods (WHO 2009; Widmer 2010). Specific policies and procedures on products and methods of surgical hand preparation should be developed locally.

PPE for surgical and dental procedures

For surgical procedures and dentistry, the sequence for putting on PPE differs from that outlined in Section B1.2. In these situations, masks and protective eyewear are applied first prior to hand preparation. Gown and gloves are then put on.

Double-gloving (wearing two sets of gloves) is becoming more common, especially for surgery where sharp surfaces are formed (such as orthopaedic or dental surgery). A second pair of gloves protects the inner pair, without apparently affecting surgical performance (Tanner & Parkinson 2006). A glove liner between the two pairs of gloves reduces breaks to the inner glove even further, and extra-thick gloves seem to be as good as two pairs (Tanner & Parkinson 2006).

Information on use of Surgical aseptic non-touch technique (ANTT), and on Standard ANTT for wound care, can be found in Sections B1.7 and B5.4.
B4.3.3 Considerations pre-procedure

- Artificial nails, nail polish and jewellery may conceal underlying soiling and impair hand decontamination, and should not be worn by healthcare workers performing or assisting in surgical procedures.

- In carrying out procedures, there is a need to minimise the risk of microbial contamination of the operating site from the environment. Although there is limited evidence concerning the use of dedicated non-sterile operating attire (scrub suits, masks, hats and overshoes) by general staff in the operating environment, it may contribute to minimising operating environment contamination and reduce the risk of surgical-site infection.

- While there is evidence to support the efficacy of preoperative showering of patients in the hospital setting as a measure to reduce the rate of surgical-site infection, there is no evidence of a difference on surgical-site infection rate between chlorhexidine as a cleansing agent and plain detergent or soap. In addition, chlorhexidine has been found not to be cost-effective for this application (NICE 2008).

- There is no evidence that hair removal from patients decreases the incidence of surgical-site infection, but it might be appropriate in some clinical circumstances.

- Antibiotic prophylaxis has been used effectively to prevent surgical-site infections for appropriate operative procedures since 1969. Prophylaxis usually involves a single dose of antibiotic often given to the patient intravenously, close to the time of surgery and differs from treatment that entails a course of antibiotics over a period of time. In common with therapeutic use, the use of antibiotics for prophylaxis carries a risk of adverse drug reactions (including *C. difficile*-associated diarrhoea) and increased prevalence of antibiotic-resistant bacteria. The choice of antibiotic prophylaxis should be based on the *Australian Therapeutic Guidelines*.

- There is evidence for the efficacy of screening for MRSA carriage and decolonisation with nasal mupirocin ointment and chlorhexidine body washes before elective surgery such as cardiac and implant surgery (Lonneke 2010).

Table B4.11: Summary of processes pre surgical procedure

| Hand preparation | • Operating team members should remove hand jewellery before operations  
|                  | • Operating team members should not wear artificial nails or nail polish during operations  
|                  | • If hands are visibly soiled, perform hand hygiene with liquid soap prior to scrubbing.  
|                  | • Remove debris from underneath fingernails using a nail cleaner, preferably under running water  
|                  | • Using a suitable antimicrobial soap, preferably with a product ensuring sustained activity, scrub hands and forearms for the length of time recommended by the manufacturer |

| Operating suite/room or procedure attire | • Operating team members must wear sterile operation or procedure attire.  
|                                          | • All operating suite/room staff who are not operating within the critical aseptic field must wear dedicated non-sterile attire in all areas where operations are undertaken.  
|                                          | • Movements in and out of the operating area should be kept to a minimum. |

| Patient preparation | • Advise patients to shower or have a bath (or help patients to shower, bath or bed bath) using soap, either the day before, or on the day of, surgery  
|                     | • Avoid routine removal of hair—if clinical circumstances require hair removal, it should be clipped on the day of surgery or as close as possible to the time of operation. Hair must never be shaved  
|                     | • Provide antibiotic prophylaxis where appropriate, in accordance with the *Australian Therapeutic Guidelines*  
|                     | • Consider screening for MRSA carriage and decolonisation with nasal mupirocin ointment and chlorhexidine body washes before elective surgery such as cardiac and implant surgery. |
B4.3.4 Considerations during a surgical procedure

- Surgical hand preparation is required to minimise the risk that resident or transient microorganisms contaminate the surgical wound. While transient microorganisms are readily removed by soap and water, antiseptics are required to eliminate resident microorganisms that reside in deep crevices and hair follicles.

- In the hospital setting, sterile gowns should be used when entering the critical aseptic field, to prevent patients from being exposed to the risk of contamination.

- There is no available evidence that double-gloving reduces the risk of surgical-site infection or that glove perforation increases the risk of surgical-site infection. However, current practice involves double-gloving in circumstances when the risk of glove perforation and its consequences for contamination of the operative field (in prosthetic surgery for example) is high.

- There is a need for safe operating suite/room practice when using alcohol-based antiseptic skin preparations prior to incision with diathermy. The evidence suggests that there is no difference between rates of surgical-site infection where diathermy is used to make an incision compared with conventional techniques. It is important to avoid pooling and wetting of drapes with the antiseptic and to let them dry before connecting the diathermy (Maiwald et al 2006).

- Although the use of non-iodophor-impregnated incise drapes is routine in some operations (such as prosthetic joint or graft surgery), they may marginally increase the risk of surgical-site infection. However, adhesive drapes may have a role in maintaining the integrity of the operative site/field.

- Evidence from small surgery-specific studies up to 20–30 years old suggest that intraoperative subcutaneous wound irrigation with povidone-iodine or with saline under pressure reduces the incidence of surgical-site infection. Although this was considered to be an adjunct to antibiotic prophylaxis in contaminated surgery, current practice has improved to make this approach unnecessary for the prevention of surgical-site infection.

- There is no evidence that intracavity lavage with antibiotics, other than a single small study of tetracycline lavage after contaminated surgery, reduces the incidence of surgical-site infection. There is some evidence that postoperative lavage of the perineal space with povidone-iodine reduces surgical-site infection.

- There is evidence that re-disinfection of the skin adjacent to the wound with iodine in alcohol solution prior to incisional closure has no effect on the incidence of surgical-site infection.

- The instillation of cefotaxime into wounds prior to closure appears to have no effect on surgical-site infection incidence after surgery for peritonitis.

- There is no robust evidence to support the use of a dressing in the immediate postoperative period for the prevention of surgical-site infection. However, it is generally accepted good clinical practice to cover the wound with an appropriate interactive dressing for a period of 2 days unless otherwise clinically indicated, for example, if there is excess wound leakage or haemorrhage.

- There is no robust evidence to support the use of one dressing over another. However, in the majority of clinical situations a semi-permeable film membrane with or without an absorbent island is preferable.
Table B4.12: Summary of processes during a surgical procedure

| Hand hygiene                              | • Perform hand hygiene before the first operation on the list using an antiseptic surgical solution, according to the manufacturer’s instructions for the product that is being used. Use a single-use brush or pick for the nails, and ensure that hands and nails are visibly clean.  
|                                          | • Before subsequent operations, perform hand hygiene using an antiseptic surgical solution. If hands are soiled during a procedure, hand hygiene should be performed again with an antiseptic surgical solution. |
| Operating suite/room attire              | • In hospital settings, wear sterile gowns during the procedure.  
|                                          | • Consider wearing two pairs of sterile gloves when there is a high risk of glove perforation. |
| Patient preparation                      | • Prepare the skin at the surgical site immediately before incision using an antiseptic preparation, preferably chlorhexidine.  
|                                          | • If diathermy is to be used, ensure that antiseptic skin preparations are dried by evaporation and there is no pooling of alcohol-based preparations.  
|                                          | • If an incise drape is required, use an iodophor-impregnated drape unless the patient has an iodine allergy. Do not use non-iodophor-impregnated incise drapes routinely for surgery as they may increase the risk of surgical-site infection. Ensure skin preparation is dry before draping the patient. |
| Wound management                         | • Avoid routine use of wound irrigation or intracavity antibiotic lavage as measures to reduce surgical-site infection.  
|                                          | • Avoid routine use of intraoperative skin re-disinfection or topical cefotaxime as measures to reduce the risk of surgical-site infection in abdominal surgery.  
|                                          | • It is recommended that at the end of the operation, surgical incisions are covered with an appropriate dressing such as semi-permeable film membrane with or without an absorbent island. |

B4.3.5 Considerations post-procedure

• There is no high-quality evidence available that supports a change to the current clinical practice of using an aseptic technique. However, the use of aseptic technique when removing or changing surgical wound dressings can minimise the risk of contaminating the site with additional microorganisms.

• There was no evidence available that examined the effects of wound cleansing solutions for the prevention of surgical-site infection.

• Not all surgical-site infections require antibiotic treatment: minor infections may respond to drainage of pus (for example, by removal of sutures) and topical antisepsis. Antibiotic therapy carries with it the risk of adverse drug reactions and the development of antimicrobial-resistant bacteria as well as the associated risk of *C. difficile* diarrhoea.

• It is good practice to discard all used operating suite/room attire prior to leaving the operating area to prevent healthcare workers, patients and visitors from being exposed to the risk of contamination.

B4.4 Putting it into practice

B4.4.1 Checklist of standard precautions for procedures

This table outlines the use of standard precautions for a range of procedures. It is assumed that there is no known or suspected infection. Decision-making about the level of protection required involves a risk assessment of the procedure to be performed; for example, usual wound irrigation is unlikely to require surgical mask and eye protection in primary care, but may be required more often in the hospital setting.

**B5 Supplementary information**

**B5.1 Recommended routine cleaning frequencies for clinical, patient and resident areas in acute settings**

The following table outlines the recommended minimum frequencies for routine cleaning of various items in healthcare facilities. It is applicable to all settings (although some items may not be relevant to all settings) and is presented by level of risk as per the key below. The table has been developed to provide a benchmark guide to best-practice cleaning schedules. Facilities should develop and implement a local cleaning schedule and policy that suits their environment, and consider regular monitoring and mechanisms to deal with specific organisms and outbreak situations. For guidance on cleaning of spills, see Section B1.4.3.

¹ Medical surface detergent or a detergent wipe that is registered as a Class I Medical Device with the TGA (for cleaning of surfaces and frequently touched objects in clinical, patient and resident areas). This detergent or detergent wipe should be recommended with clear instructions in regards to materials compatibility.

2 Where transmission-based precautions are required, a TGA-registered hospital grade disinfectant must be used if a disinfectant is required. The disinfectant chosen should have label claims against the organism of concern.

B5.3 Exposure prone procedures (EPP)\textsuperscript{24}

Exposure prone procedures (EPPs) are invasive procedures where there is potential for direct contact between the skin, usually finger or thumb of the healthcare worker, and sharp surgical instruments, needles, or sharp tissues (e.g. fractured bones), spicules of bone or teeth in body cavities or in poorly visualised or confined body sites, including the mouth of the patient.

During EPPs, there is an increased risk of transmitting bloodborne viruses between healthcare workers and patients.

EPP categories

The nature of the EPP performed by the healthcare worker can be categorised according to level of risk of transmission, in increasing order of magnitude.

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Category 1</td>
<td>A procedure where the hands and fingertips of the healthcare worker are usually visible and outside the body most of the time and the possibility of injury to the worker’s gloved hands from sharp instruments and/or tissues is slight. This means that the risk of the healthcare worker bleeding into a patient’s open tissues should be remote, e.g. insertion of a chest drain.</td>
</tr>
<tr>
<td>Category 2</td>
<td>A procedure where the fingertips may not be visible at all times but injury to the healthcare worker’s gloved hands from sharp instruments and/or tissues is unlikely. If injury occurs it is likely to be noticed and acted upon quickly to avoid the healthcare worker’s blood contaminating a patient’s open tissues, e.g. appendicectomy.</td>
</tr>
<tr>
<td>Category 3</td>
<td>A procedure where the fingertips are out of sight for a significant part of the procedure, or during certain critical stages and in which there is a distinct risk of injury to the healthcare worker’s gloved hands from sharp instruments and/or tissues. In such circumstances it is possible that exposure of the patient’s open tissues to the healthcare worker’s blood may go unnoticed or would not be noticed immediately, e.g. hysterectomy.</td>
</tr>
</tbody>
</table>

Advice on EPPs in specific areas of clinical care

*Accident and emergency (A&E)*

A&E staff members who are restricted from performing EPPs should not provide pre-hospital trauma care. These staff should not physically examine or otherwise handle acute trauma patients with open tissues because of the unpredictable risk of injury from sharp tissues. Cover from colleagues who are allowed to perform EPPs would be needed at all times to avoid this eventuality.

Other EPPs which may arise in an A&E setting would include:

- rectal examination in presence of suspected pelvic fracture
- deep suturing to arrest haemorrhage
- internal cardiac massage.

(See also Anaesthetics, Biting, Paramedics and Resuscitation)

\textsuperscript{24} This section has been adapted by the committee from DH/HP/GHP3 (2005) HIV Infected Health Care Workers: Guidance on Management and Patient Notification. London: UK Dept Health.
Anaesthetics

Endotracheal intubation, use of a laryngeal mask and procedures performed purely percutaneously are not exposure prone. The only procedures currently performed by anaesthetists which would constitute EPPs are:

- the placement of portacaths (very rarely done) which involves excavating a small pouch under the skin and may sometimes require manoeuvres which are not under direct vision
- the insertion of chest drains in accident and emergency trauma cases such as patients with multiple rib fractures.

The insertion of a chest drain may or may not be considered to be exposure prone depending on how it is performed. Procedures where, following a small initial incision, the chest drain with its internal trochar is passed directly through the chest wall (as may happen e.g. with a pneumothorax or pleural effusion) and where the lung is well clear of the chest wall, would not be considered to be exposure prone. However, where a larger incision is made, and a finger is inserted into the chest cavity (e.g. with a flail chest) and where the healthcare worker could be injured by the broken ribs, the procedure should be considered exposure prone.

Modern techniques for skin tunnelling involve wire guided techniques and putting steel or plastic trochars from the entry site to the exit site where they are retrieved in full vision. Therefore skin tunnelling is no longer considered to be exposure prone (see also Arterial cutdown).

Arterial cutdown

Although the use of more percutaneous techniques has made arterial or venous cutdown to obtain access to blood vessels an unusual procedure, it may still be used in rare cases. However, as the operator’s hands are always visible, it should no longer be considered exposure prone.

Biting

Staff working in areas where there is a significant risk of being bitten should not be considered to be performing EPPs.

Bone marrow transplants

Not exposure prone.

Cardiology

Percutaneous procedures including angiography/cardiac catheterisation are not exposure prone. Implantation of permanent pacemakers (for which a skin tunnelling technique is used to site the pacemaker device subcutaneously) may or may not be exposure prone. This will depend on whether the operator’s fingers are or are not concealed from view in the patient’s tissues in the presence of sharp instruments during the procedure (see also Arterial cutdown).

Dentistry

The definition for exposure-prone procedures for dentistry is currently under review. The guideline will be updated once this issue is resolved.

Ear, nose and throat surgery (otolaryngology)

ENT surgical procedures generally should be regarded as exposure prone with the exception of simple ear or nasal procedures, and procedures performed using endoscopes (flexible and rigid) provided fingertips are always visible. Non-exposure prone ear procedures include stapedectomy/stapedotomy, insertion of ventilation tubes and insertion of a titanium screw for a bone anchored hearing aid.
**Endoscopy**

Simple endoscopic procedures (e.g. gastroscopy, bronchoscopy) have not been considered exposure prone. In general there is a risk that surgical endoscopic procedures (e.g. cystoscopy, laparoscopy – see below) may escalate due to complications that may not have been foreseen and may necessitate an open EPP. The need for cover from a colleague who is allowed to perform EPPs should be considered as a contingency (see also Biting).

**General practice**

See Accident and Emergency, Biting, Minor Surgery, Midwifery/Obstetrics, Resuscitation

**Gynaecology (see also laparoscopy)**

Open surgical procedures are exposure prone. Many minor gynaecological procedures are not considered exposure prone, examples include dilatation & curettage (D& C), suction termination of pregnancy, colposcopy, surgical insertion of depot contraceptive implants/devices, fitting intrauterine contraceptive devices (coils), and vaginal egg collection **provided fingers remain visible at all times when sharp instruments are in use**. Performing cone biopsies with a scalpel (and with the necessary suturing of the cervix) would be exposure prone. Cone biopsies performed with a loop or laser would not in themselves be classified as exposure prone, but if local anaesthetic was administered to the cervix other than under direct vision (i.e. with fingers concealed in the vagina), then the latter would be an EPP (category 1).

**Haemodialysis/Haemofiltration**

See Renal Medicine

**Intensive care**

Intensive care does not generally involve EPPs on the part of medical or nursing staff

**Laparoscopy**

These are mostly non-exposure prone because fingers are never concealed in the patient’s tissues. Exceptions are: if main trochar inserted using an open procedure, as for example in a patient who has had previous abdominal surgery. Also exposure prone if rectus sheath closed at port sites using J-needle, and fingers rather than needle holders and forceps are used. In general there is a risk that a therapeutic, rather than a diagnostic, laparoscopy may escalate due to complications, which may not have been foreseen necessitating an open EPP. Cover from colleagues who are allowed to perform EPPs would be needed at all times to avoid this eventuality.

**Midwifery/obstetrics**

Simple vaginal delivery, amniotomy using a plastic device, attachment of foetal scalp electrodes, infiltration of local anaesthetic prior to an episiotomy and the use of scissors to make an episiotomy cut are not exposure prone. The only EPPs routinely undertaken by midwives are repairs following episiotomies and perineal tears: category 1 in the case of first-degree lacerations; category 2 in the case of second, third and fourth degree lacerations. Repairs of third and fourth degree tears are normally undertaken by medical staff members who may include general practitioners assisting at births in a community setting.

**Minor surgery**

In the context of general practice, minor surgical procedures such as excision of sebaceous cysts, skin lesions, cauterisation of skin warts, aspiration of bursae, cortisone injections into joints and vasectomies do not usually constitute EPPs.
Sharps occupational exposure

Healthcare workers need not refrain from performing EPPs pending follow up of occupational exposure to a BBV infected source. The combined risks of contracting a BBV from the source patient and then transmitting this to another patient during an EPP is so low as to be considered negligible. However in the event of the worker being diagnosed with a BBV, such procedures should cease in accordance with this guidance.

Nursing

General nursing procedures do not include EPPs. The duties of operating room nurses should be considered individually. Instrument nurses do not generally undertake EPPs. However, it is possible that nurses acting as first assistant may perform EPPs (see also Accident and Emergency, Renal Medicine/Nursing, and Resuscitation).

Obstetrics/Midwifery

See Midwifery/Obstetrics. Obstetricians perform surgical procedures, many of which will be exposure prone according to the criteria.

Operating room technicians

General duties do not normally include EPPs.

Ophthalmology

With the exception of orbital surgery, which is usually performed by maxillo-facial surgeons (who perform many other EPPs), routine ophthalmological surgical procedures are not exposure prone as the operator’s fingers are not concealed in the patient’s tissues. Exceptions may occur in some acute trauma cases, which should be avoided by EPP restricted surgeons.

Optometry

The training and practice of optometry does not require the performance of EPPs.

Orthodontics

See Dentistry

Orthopaedics

EPPs
- Open surgical procedures
- Procedures involving the cutting or fixation of bones, including the use of K-wire fixation and osteotomies
- Procedures involving the distant transfer of tissues from a second site (such as in a thumb reconstruction)
- Acute hand trauma
- Nail avulsion of the toes for in-growing toenails and Zadek’s procedure.
Non-EPPs

- Manipulation of joints with the skin intact
- Arthroscopy, provided that if there is any possibility that an open procedure might become necessary, the procedure is undertaken by a colleague able to perform the appropriate open surgical procedure
- Superficial surgery involving the soft tissues of the hand
- Work on tendons using purely instrumental tunnelling techniques that do not involve fingers and sharp instruments together in the tunnel
- Procedures for secondary reconstruction of the hand, provided that the operator's fingers are in full view
- Carpal tunnel decompression provided fingers and sharp instruments are not together in the wound
- Closed reductions of fractures and other percutaneous procedures.

Paediatrics

Neither general nor neonatal/special care paediatrics has been considered likely to involve any EPPs. Paediatric surgeons do perform EPPs (see also Arterial cutdown).

Paramedics

In contrast to other emergency workers, a paramedic's primary function is to provide care to patients. Paramedics do not normally perform EPPs. However, paramedics who would be restricted from performing EPPs should not provide pre-hospital trauma care. This advice is subject to review as the work undertaken by paramedics continues to develop (see also Accident & Emergency, Biting and Resuscitation).

Pathology

In the event of injury to an EPP restricted pathologist performing a post mortem examination, the risk to other workers handling the same body subsequently is so remote that no restriction is recommended.

Podiatrists

Routine procedures undertaken by podiatrists who are not trained in and do not perform surgical techniques are not exposure prone. Procedures undertaken by podiatric surgeons include surgery on nails, bones and soft tissue of the foot and lower leg, and joint replacements. In a proportion of these procedures, part of the operator's fingers will be inside the wound and out of view, making them EPPs (see also Orthopaedics).

Radiology

All percutaneous procedures, including imaging of the vascular tree, biliary system and renal system, drainage procedures and biopsies as appropriate, are not EPPs (see also Arterial cutdown).

Renal medicine

These procedures are not exposure prone and neither haemofiltration nor haemodialysis constitute EPPs. The working practices of those staff members who supervise haemofiltration and haemodialysis circuits do not include EPPs.

Resuscitation

Resuscitation performed wearing appropriate protective equipment does not constitute an EPP.
**Surgery**

Open surgical procedures are exposure prone. This applies equally to major organ retrieval because there is a very small, though remote, risk that major organs retrieved for transplant could be contaminated by a healthcare worker’s blood during what are long retrieval operations while the patient’s circulation remains intact. It is possible for some contaminated blood cells to remain following pre-transplantation preparatory procedures and for any virus to remain intact since organs are chilled to only 10°C (see also Laparoscopy, Minor Surgery).

**Volunteer healthcare workers (including first aid)**

The important issue is whether or not an infected healthcare worker undertakes EPPs.

### B5.4 Examples of how to perform aseptic non-touch technique

#### B5.4.1 ANTT for peripheral and central access intravenous therapy

Typically, IV maintenance procedures will be assessed as requiring Standard ANTT with the employment of a main general aseptic field and critical micro aseptic fields.

**Figure B5.1:** Aseptic non-touch technique for peripheral and central access intravenous therapy
## Aseptic non-touch technique for peripheral and central access intravenous therapy

<table>
<thead>
<tr>
<th>Step</th>
<th>Task Description</th>
</tr>
</thead>
</table>
| 1    | Perform hand hygiene  
This will break any potential transmission of infection from the clinical ward environment to the clean preparation area/room. Effective hand hygiene is vital to reduce the risk of contaminating key parts/sites. |
| 2    | Use a clean tray  
Such a tray provides a sufficiently large, robust and controlled working area. Reprocess re-usable trays according to local policy. |
| 3    | While the tray is drying, gather equipment  
Hands are contaminated when gathering equipment from storage cupboards etc. It’s important therefore to gather all equipment before performing hand hygiene at Step 4. Gathering equipment at this point also allows the tray to dry properly and saves a little time. |
| 4    | Perform hand hygiene  
This occurs immediately before assembly of equipment and the preparation of drugs. This way, hands are optimally clean prior to glove application and non-touch technique key part manipulation. |
| 5    | Apply non-sterile gloves (use sterile gloves if you must touch key parts)  
Primarily, gloves are worn to protect the user from drug exposure and blood products. All peripheral and central access IV procedures should be performed without touching key parts. Therefore, non-sterile gloves will nearly always be the logical and efficient glove choice. In the event the healthcare worker unknowingly touches a key part, non-sterile gloves also act as a safety net as they are typically cleaner than skin. |
| 6    | Assemble equipment and prepare medications—protect key parts using non-touch-technique  
A non-touch technique is the most important component of aseptic practice because a key part cannot be contaminated directly if it is not touched. Key parts should be protected throughout the procedure when they are not in use. This can be achieved by using sterilised IV bungs or the inside of syringe packets. Both systems provide critical micro aseptic fields around the key part. |
| 7    | User assessment:  
If gloves become contaminated — decontaminate hands and re-glove  
This is necessary when it is not possible to proceed from preparation to administration without contaminating gloved hands (e.g. due to prepping a patient).  
If gloves remain uncontaminated between steps 6 & 7 proceed directly to step 7  
Where it is possible to retain the asepsis of gloved hands between preparation and administration, the user does not need to decontaminate hands between administration and preparation. This will promote compliance and save time. |
| 8    | Clean key parts  
2% chlorhexidine/70% alcohol wipes is the application of choice (Pratt et al 2007). In addition, the benefit of using friction and allowing key parts to dry has been demonstrated by Kaler & Chinn (2007).  
**Method:**  
A large 2% chlorhexidine and 70% alcohol wipe should be fully unfolded to provide a suitable working surface area.  
One side of the wipe should be exposed to the user’s gloved hand, the other side should be introduced to the hub (non-touch technique).  
The port tip should be thoroughly wiped hard for 5 seconds—to create friction.  
This should be repeated 4 times using different parts of the tissue (to remove dirt from the tip).  
After cleaning the hub clean the sides of the port and line, working away from the port tip.  
Allowing the hub to air dry promotes asepsis.  
This technique provides the required level of friction. Using different parts of the wipe ensures any dirt is transferred from the hub to the wipe. The hub must dry before use otherwise it won’t be aseptic (if organisms have remained, a wet tip will facilitate their transportation into the patient on injection). |
9 **Administer medication using non-touch technique**
Key parts cannot be contaminated by contact if they are not touched. A non-touch technique should therefore be used even if the user is wearing sterile gloves (because once sterile gloves are open to air they are no longer sterile, and can also be inadvertently contaminated by touch). If necessary, a small sterilised towel can be placed under a patient’s line to promote safe handling.

10 **Dispose of sharps and equipment then dispose of gloves**
Sharps are best disposed of at the bedside if possible (on the basis that the quicker they are disposed of the less chance there is of an accident).

11 **Clean tray**
Re-usable trays are reprocessed at the end of the procedure to prevent cross infection between patients and staff. Trays are reprocessed according to local policy.

12 **Perform hand hygiene**
It is essential that the post-procedure hand hygiene is performed immediately after glove removal i.e. before contact with the environment (because gloves encourage the hands to sweat-out organisms from the skin).

**B5.4.2 Aseptic non-touch technique for wound care**

Wound care procedures are highly variable. Typically, a critical main aseptic field is employed and practice is dictated accordingly.

**Figure B5.2:** Aseptic non-touch technique for wound care
Table B5.2: Aseptic non-touch technique for wound care

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
</table>
| 1 | **With clean hands clean trolley surfaces**  
   | Clean surface according to local policy to reduce the risk of aseptic field contamination. |
| 2 | **Gather dressing pack and equipment, place on bottom shelf**  
   | Hands are contaminated when gathering equipment from storage cupboards etc. It’s important therefore to gather all equipment before the next hand hygiene. Gathering equipment at this point also allows the trolley to dry properly and saves a little time. |
| 3 | **Perform hand hygiene**  
   | This occurs immediately before assembly of the aseptic field drape and equipment etc in order to promote asepsis. |
| 4 | **Open pack, place drape on top shelf and position waste bag** |
| 5 | **Assemble equipment and position onto top shelf, protecting key parts** |
| 6 | **Apply non-sterile gloves**  
   | Non-sterile gloves are indicated because Steps 7 and 8 do not involve the touching of key sites or key parts. |
| 7 | **Position a paper towel or drape under the wound**  
   | This will promote asepsis and help protect the surrounding environment from contamination. |
| 8 | **Remove dressing, expose wound and dispose of dressing into waste bag**  
   | Disposing of the dressing here limits the movement of contaminated waste, helping to protect the wider clinical or community environment. |
| 9 | **Perform hand hygiene**  
   | Steps 7 and 8 are ‘dirty’ procedures and hand hygiene will promote asepsis. |
| 10 | **Apply sterile gloves**  
   | Although not essential for some small, minor dressings, sterile gloves at this stage will help promote asepsis of the wound. NB: Sterile gloves are essential at this stage if the wound requires touching directly with gloved hands. |
| 11 | **Clean wound using non-touch technique**  
   | A non-touch technique will help protect the wound from colonisation or infection. |
| 12 | **Dress wound using non-touch technique**  
   | A non-touch technique will help protect the wound from colonisation or infection. |
| 13 | **Dispose of equipment, waste and gloves**  
   | Folding the used equipment and waste into the aseptic field drape and disposing it in the attached waste bag will minimise the movement of waste and protect the wider working environment. |
| 14 | **Clean trolley surfaces**  
   | Cleaning according to local policy will prevent cross infection. |
| 15 | **Perform hand hygiene**  
   | This will help break any chain of potential cross infection. |
B5.5 General infection control resources

B5.5.1 International guidelines on infection control

- Centers for Disease Control and Prevention - Infection Control in Healthcare Settings  
  http://www.cdc.gov/ncidod/dhqp/us
- epic2: National Evidence-Based Guidelines for Preventing Healthcare-Associated Infections in NHS Hospitals in England

- Society for Healthcare Epidemiology of America (SHEA) http://www.shea-online.org/
PART C

ORGANISATIONAL SUPPORT

Summary

For infection prevention and control to be effective at the clinical level, much organisational support is required. This includes embedding infection control into governance and management structures, initiating procedures (e.g. immunisation programs) to ensure that healthcare workers are protected, instituting processes for surveillance that feed into the overall quality control program, implementing systems for ongoing staff education and training, and incorporating infection control into planning for facility design and maintenance.

Infection control is a health and safety issue, which means that all those working in the healthcare facility—managers, healthcare workers and support staff—are responsible for providing a safe environment for patients and other staff. Organisational support should aim to ensure that clinical work practices provide patient-centred care—this is not only essential from a safety and quality perspective but out of consideration for patient preferences. This may require consultation with patients and relevant consumer groups in the development of health care services.

The information presented in this Part is particularly relevant to managers of healthcare facilities. It outlines responsibilities of management of healthcare facilities, including governance structures that support the implementation, monitoring and reporting of effective work practices. While the focus of the information is acute-care facilities, much of the information is relevant in other healthcare settings.
C1  Management and clinical governance

Summary
To be effective, infection prevention and control must be a priority in every healthcare facility—this requires total commitment at every level of the organisation.

- Organisational capacity is achieved by having appropriate governance and management structures. This means that managers are aware of the healthcare facility’s performance in terms of infection transmission and there are systems in place to prevent the transmission of infection, reduce risk and address problems when they arise.
- The management structure and processes associated with infection control will differ depending on the size of the organisation and the types of healthcare services it delivers. However, the principles of clinical governance apply regardless of the setting and all essential roles and responsibilities should be fulfilled.
- The person in charge of the organisation (e.g. chief executive officer [CEO] of a hospital, principal of an office-based practice) must have overall responsibility for and direct involvement in the organisation’s infection prevention and control program.
- There must be adequate resourcing for dedicated infection control staff, and resources to run the infection prevention and control program including professional development.
- Each organisation should define the outcome measures for monitoring infection prevention and control policies (see Section C4).
- All employees should understand their roles and responsibilities and have appropriate training to maintain a safe work environment (see Section C3).
- Patient-centred health care is safer health care—patients’ healthcare rights must be considered during the development of programs, policies and procedures.

C1.1  Clinical governance in infection prevention and control

Addressing infection prevention and control requires a facility wide program and is everybody’s responsibility. Healthcare facilities have a legal responsibility to provide a safe work environment, safe systems of work and a safe environment for patients and visitors. Clinical governance refers to the system by which managers and clinicians in each healthcare facility share responsibility and are held accountable for patient care. This involves minimising risks to patients and staff, and continuously monitoring and improving the quality of clinical care.

Preventing transmission of infectious agents should be a priority in every healthcare facility. This will involve action to:

- develop a facility-wide strategic plan for infection prevention and control
- establish a system to manage infection prevention and control (such as a committee) with input from across the spectrum of clinical services and management, and a mechanism for considering patients’ feedback
- appoint infection control professionals and support their continuing professional development (e.g. attendance at relevant state or national professional organisation meetings)
- incorporate infection prevention and control into the objectives of the facility’s patient and occupational safety programs
- provide administrative support, including fiscal and human resources, for maintaining infection prevention and control programs
- provide adequate staff training and protective clothing and equipment, and arrange workplace conditions and structures to minimise potential hazards.

All healthcare workers need to be aware of their individual responsibility for maintaining a safe care environment for patients and other staff.
C1.2 Roles and responsibilities

Management and clinical governance can have a positive impact on the effectiveness of infection prevention and control, by driving continuous quality improvement and promoting a non-punitive culture of trust and honesty (Victorian Quality Council 2004). Studies have found that where clinical governance and management encourage collaboration between healthcare managers and clinicians, change is more likely to be achieved than where there is unilateral governance (Ham 2003). Change is also more likely to be achieved and sustained when the role of patients as partners in their health care is strengthened, and where there is a shared understanding of the role of patients, healthcare workers and organisations in achieving the best possible outcomes (ACSQHC 2008).

The roles and responsibilities described below are most relevant to acute health care settings. However, all the roles described in this section are important for effective infection prevention and control and can be readily adapted to other healthcare settings—for example, with the practice principal fulfilling relevant roles and responsibilities of a CEO, and the office manager or other staff representative with an interest in infection prevention and control fulfilling the role of infection control professional (see Section C1.2.4).

C1.2.1 Chief Executive Officer/Administrator

The healthcare facility’s CEO or designated equivalent administrator should support and promote infection prevention and control as an integral part of the organisation’s culture through the following strategies:

• having a performance agreement that includes infection prevention and control outcomes as a key performance indicator
• endorsing the inclusion of specific articulated infection prevention and control roles, responsibilities and accountabilities for relevant staff within the facility’s management plan
• attending and participating in each Infection Prevention and Control (IPC) Committee meeting
• ensuring that infection control professionals are resourced
  – in terms of co-workers, information technology, access to up-to-date information, designated office/ work space and tools to meet relevant infection prevention-related legislative, regulatory and accreditation requirements
  – to achieve negotiated healthcare-associated infection reduction targets and to perform the essential tasks outlined in Section C1.2.2 below
• ensuring that the healthcare facility’s IPC program includes involvement of one or more medical practitioners to support and play a shared leadership role
• ensuring that the rights of patients, as articulated in the Australian Charter of Healthcare Rights (ACSQHC 2008), are integral to the IPC program
• committing to the IPC program vision, mission, priorities, targets and annual infection prevention and control plan with specific, measurable goals for healthcare-associated infection risk mitigation and reduction—these should be outlined in an annual business plan which the CEO (or his or her designate) and the infection control professional jointly develop
• supporting an organisational culture that promotes individual responsibility for infection prevention and control among all staff and values the IPC program contribution to the safety of patients, healthcare workers and others—this support includes ensuring IPC program staffing levels are sufficient and incorporating responsibility for infection prevention and control into every staff member’s job description
• authorising infection control professionals to:
  – implement IPC program recommendations
  – intervene when clinical or other practices pose infection risks (e.g. halt building
    and construction activities, close units during outbreaks and guide patient placement
    for isolation or cohorting)
• recommending remedial action when infection prevention and control measures
  are compromised or breached.

In some Australian states and territories and internationally, performance against infection control
indicators is monitored. For example, in Tasmania, a performance monitoring process is in place.
The indicators used to monitor performance and progress includes indicators relating to infection
prevention and control.

C1.2.2 Infection control professionals

Infection control professionals should have the skills, experience and qualifications relevant
to their specific clinical setting and be able to:
• develop, manage and evaluate governance of infection prevention and control systems,
  related programs and services
• provide expert infection prevention consultancy and strategic direction to the healthcare
  facility and external agencies.

Infection control professionals are primarily responsible for designing, coordinating, implementing and
undertaking ongoing evaluation of the facility's infection prevention and control program and policies,
including compliance with the respective state/territory and/or national accreditation, licensing, policy
or regulatory requirements. They are also responsible for equipment and product evaluation.

Infection control professionals need to be supported by the facility with resources, authority and
time to maintain clinical and professional currency (including support for credentialling and have
preferably a postgraduate qualification [see Section C3.5.2]).

Infection control professionals must be involved in decisions on facility construction and
design, patient placement ratios (e.g. single rooms, negative pressure rooms) and environmental
assessments (see Section C6).

The infection control professional’s performance should be appraised at least annually, along with
negotiation of individual professional development goals, support, opportunities and plan of work.

C1.2.3 Infection prevention and control committee

A multidisciplinary IPC Committee should review and guide the healthcare facility's IPC program,
strategies and plans. Membership must include, but not be limited to: the CEO or his/ her
designate; an executive member with the authority to allocate the necessary resources and take
remedial action as needed from time to time; an infection control professional; and one or more
medical practitioners (preferably a clinical microbiologist and/or an infectious diseases physician).

The meeting frequency and content will depend on the facility's size, case-mix complexity
and the infection risk of populations serviced. IPC Committee activity should be measured
against an operational plan with set priorities to target within key focus areas.

The IPC Committee should have a formal mechanism for regularly considering patients’
experiences and feedback and modifying the IPC program accordingly.
The IPC Committee should have an organisational communication strategy to facilitate day-to-day activities and reporting activities, which should be able to be escalated in response to an incident or outbreak. Regular and ad-hoc communication processes should exist between the IPC team and relevant public health authorities.

Healthcare facilities that do not have access to an IPC committee (or infection control professional) should consult with an infection control professional in a larger health service for program advice and support.

C1.2.4 Infection prevention and control processes in office-based practice

In office-based practice, the processes associated with infection prevention and control will differ although the responsibilities are the same. The principal of the practice is equivalent to the CEO; he or she has overall responsibility for infection prevention and control in the practice and should demonstrate a strong commitment to an agreed infection prevention and control plan based on the identified risks for that practice. Local policies and procedures need to be developed and implemented as part of standard operating procedures. A nominated staff member must take on the role of infection control professional, developing infection prevention and control procedures and overseeing their implementation. This staff member is likely to need additional training and perhaps ongoing external support in managing infection prevention and control issues. Infection prevention and control should be considered at every staff meeting, with discussion of procedures and processes of the practice and any problem areas.

C1.3 Infection prevention and control program

The IPC program is the means by which infection prevention and control practice is implemented in every part of the healthcare facility. Elements of an IPC program include:

• development of a risk-management policy for the facility (see Section C1.4)
• development of infection prevention and control policies and procedures that are based on national and/or state/territory guidelines and relevant to the healthcare facility and clinical area/department (including risk management)
• education and training of staff so that they can implement the policies and procedures
• oversight of the implementation of policies and procedures
• development of a monitor and review process to ensure that policies and procedures are being implemented correctly (e.g. completion of checklists during care provision, log books)
• oversight of surveillance of:
  – specific organisms that are relevant to the local environment (this may require consultation with infectious diseases specialists or epidemiologists)
  – surgical-site infections and other device-related infections
  – notifiable diseases.

The IPC program may also include antibiotic stewardship initiatives run in conjunction with the pharmacy department/services.
C1.3.1 Recommendations including policies and procedures

National and/or state infection prevention and control recommendations relevant to the facility should be endorsed and their principles applied as necessary according to local need by the IPC Committee. Compliance with these recommendations must be monitored. At a minimum, these recommendations form the basis of the infection control professional's directives, which should be easily accessible in hard copy, electronic or other formats. Suggested topics to be addressed, depending on the facility, include:

- hand hygiene
- standard and transmission-based precautions, including:
  - aseptic technique and prevention of device-related infections and other healthcare-associated infections (e.g. surgical-site infections, IVD-related bloodstream infections)
  - environmental cleaning and disinfection (with Environmental Services)
  - reprocessing of reusable equipment and supplies (with Reprocessing Services)
  - safe management of clinical and related waste and sharps
- healthcare-associated infection surveillance
- communicable disease post-exposure management and follow-up
- outbreak management, including systems to designate patients known to be colonised or infected with a targeted MRO and to notify receiving healthcare facilities and personnel before transfer of such patients within or between facilities
- critical incident management and investigation
- epidemiologically significant organisms (including MROs)
- use of appropriate infection prevention and control measures (including transmission-based precautions) of potentially infectious persons at initial points of patient encounter such as at the time of admission and in the outpatient settings (triage areas, emergency departments, outpatient clinics, clinicians' offices)
- prevention and management of bloodborne pathogen exposure
- surge capacity for novel respiratory and other communicable disease emergencies (with emergency response committees and outbreak management teams)
- construction/ refurbishment/ engineering.

C1.3.2 Infection prevention measures

To implement the measures outlined in infection prevention and control policies and procedures, the facility must have access to an accredited (e.g. National Association of Testing Authorities [NATA]) laboratory and pharmacy staff, as well as systems, protocols and resources to:

- implement the recommendations included in national and state/territory guidelines
- perform surveillance and auditing
- provide regular, meaningful feedback of HAI data to individual clinicians, specific specialty departments/units, quality improvement, senior management and others as stipulated in the annual IPC program business plan
- implement and participate in periodic intensive local, state, national or global HAI reduction campaigns including application of recommendations for healthcare-associated infection surveillance and reporting
- ensure collaboration between the infection control professional and other stakeholders such as infectious disease and pharmacy departments to support antibiotic stewardship
• collaborate with product and device committees to assess the infection prevention implications of new devices, procedures and technologies

• provide education regarding infection prevention core principles to all new staff and to existing staff at least annually

• provide advice and information to staff regarding new and emerging infectious disease threats and trends

• have a process for engaging patients in the safety of their healthcare by routinely:
  – providing advice and education related to specific and general healthcare-associated infection prevention to patients and families (e.g. brochures, pamphlets, face-to-face discussions, information sheets)
  – asking patients and families for feedback about their care.

### C1.3.3 Quality improvement

Safe and high quality infection prevention and control practices contribute to continual improvements in the quality of healthcare provided in any setting. These practices occur at the organisational, staff and patient levels.

IPC programs include principles of quality management, through the use of approaches such as plan-do-study-act that enable processes to be enhanced and improved. It is essential to performance improvement that healthcare workers understand the value of monitoring and evaluating their own clinical practice. Examining patient and carer experiences can provide an insight into their perspectives and allow these to be taken into account in improving the quality of care.

Integrating monitoring and review processes into policies and procedures (e.g. through infection prevention and control audits) enables data to be collected. Performance indicators can be developed from this, such as surveys on compliance with protocols and monitoring the use of infection prevention and control products.

In the acute setting, it is recommended that healthcare facilities support local research regarding specific cases of infection, outbreaks or preventative strategies, and adopt relevant research findings that reduce or prevent healthcare-associated infections. In addition, comprehensive and epidemiologically sound systems, protocols and resources should exist to:

• actively manage all infection prevention components of accreditation
• design, undertake and respond to results of periodic audits and formal reviews of relevant clinical practice and performance (e.g. antibiotic use, hand hygiene compliance, cleaning)
• collaborate with Clinical Risk Departments and Executive Staff to develop appropriate methods for rapid response, remediation, investigation and evaluation of infection prevention critical incidents (e.g. sterilisation or disinfection failures)
• provide basic, minimum infection prevention and control education to staff, healthcare workers and volunteers appropriate to their roles, risks and the services provided by the healthcare facility
• include patient feedback on their care as an integral part of quality improvement.

Surveillance and healthcare-associated infection monitoring strategies should be designed and driven according to local activity, performance and trends in the incidence of epidemiologically significant organisms.

A useful resource is the ACSQHC *Measurement for improvement tool kit*, which provides a set of practical methods to measure the safety and quality of clinical health care services.25

---

C1.3.4 Resource allocation

Healthcare facility managers should ensure that there are sufficient human and fiscal resources available to support all aspects of the IPC program, including:

- providing specific infection prevention and control full-time equivalents, determined according to the scope of the IPC program, the complexity of the healthcare facility, the characteristics of the patient population and the needs of the facility and community (office-based practices may choose to attribute responsibilities and functions relating to infection prevention and control to a particular staff member)

- meeting occupational health needs related to infection prevention and control (e.g. provision of appropriate technologies and protective personal equipment, healthcare worker immunisation, post-exposure evaluation and care, evaluation and management of healthcare workers with communicable infections)

- in a hospital setting, providing clinical microbiology laboratory support, including a sufficient number of medical technologists trained in microbiology, appropriate to the healthcare setting, for detecting endemic and emerging pathogens, monitoring transmission of microorganisms, planning and conducting epidemiologic investigations

- funding surveillance cultures, rapid diagnostic testing for viral and other selected pathogens, preparation of antibiotic susceptibility summary reports and trend analysis.

C1.4 Risk management

Risk management is the basis for preventing and reducing harm arising from healthcare-associated infections and underpins the approach to infection prevention and control throughout these guidelines. Within a healthcare facility, a successful approach to risk management includes action at the organisational level (for example providing support for effective risk management through an organisational risk-management policy, staff training and monitoring and reporting) as well as in clinical practice.

C1.4.1 Organisational support for risk management

For risk management within an organisation to be effective there needs to be appropriate infrastructure and culture; a logical and systematic approach to implementing the required steps (outlined in C1.4.2); and embedding of risk-management principles into the philosophy, practices and business processes of an organisation, rather than it being separate activity or focus. Factors that support risk management across the organisation include development of a risk-management policy; staff training in risk management; implementation of a risk register, risk treatment schedule and integrated action plans; monitoring and audit; and risk-management reporting.

An infrastructure and environment that encourages two-way communication between management and healthcare workers and among healthcare workers is an important factor in increasing the level of support for and compliance with IPC programs. Management should:

- provide direction (e.g. nominate issues for attention that are relevant to the core business of the organisation, such as respiratory hygiene and cough etiquette in general practice, prevention of diarrhoeal disease in paediatrics, appropriate management of urinary catheters in spinal injury care)

- establish and evaluate periodic goals (i.e. nominate reduced rates for performance improvement)

- seek feedback on policy directives particularly in regards to changes in clinical care protocols or new technologies and how patients can be involved in policy formation

- provide information to individuals, self-directed work groups, patients and other stakeholders, with an emphasis on continually improving performance.

Healthcare workers can contribute to the development of risk-management structures, and are
integral to the strategies within these. Strategies to assist individual healthcare workers to reduce risk are included at the end of each section of Part B.

C1.4.2 A stepwise approach to risk management

The Australian/New Zealand Standard on Risk Management (AS/NZS ISO 31000:2009) outlines a stepwise approach to risk management:

- **establishing the context**—identifying the basic parameters in which risk must be managed (e.g. the type of healthcare facility, the extent of and support for the facility's infection prevention and control program)
- **avoiding risk**—establishing whether there is a risk and whether potential risk can be averted (e.g. by questioning whether a procedure is necessary)
- **identifying risks**—a systematic and comprehensive process that ensures that no potential risk is excluded from further analysis and treatment (e.g. using root cause analysis [see below])
- **analysing risks**—considering the sources of risk, their consequences, the likelihood that those consequences may occur, and factors that affect consequences and likelihood (e.g. existing controls)
- **evaluating risks**—comparing the level of risk found during the analysis process with previously established risk criteria, resulting in a prioritised list of risks for further action
- **treating risks**—selecting and implementing appropriate management options for dealing with identified risks (for example modifying procedures, protocols or work practices; providing education; and monitoring compliance with infection prevention and control procedures).

An example of the application of this approach is given in Section A2.2.

C1.5 Taking an organisational systems approach to infection prevention quality and safety

Addressing infection prevention and control issues requires a multi-component, facility-wide program and is everybody's responsibility. This section gives an outline of a systematic approach that has been shown to be effective (care bundles), together with examples of the organisational support required at facility level to address two crucial areas of infection prevention and control—reducing sharps injuries to healthcare workers and lowering the incidence in patients of bloodstream infections associated with intravascular devices. C2 to C6 discuss the separate aspects of a systems approach to infection prevention and control.

C1.5.1 Care bundles

'Care bundling' is an approach developed by the US Institute of Healthcare Improvement (IHI) to improve consistency of practice in healthcare facilities, particularly for conditions and procedures known to increase patients' risk of healthcare-associated infections. While large studies have not yet been undertaken, the approach has been shown to reduce healthcare-associated infections within hospitals and is now used widely, particularly in the US and UK.

A 'care bundle' is set of four or five evidence-based processes that aims to tie routine processes together into a cohesive unit that must be adhered to for every patient. The keys to the bundle strategy's success are the standardised and unvarying application of bundle practices, the use of multidisciplinary rounds, and daily tracking and auditing of compliance.

Care bundles can be used to monitor care and to feedback care bundle results to clinical staff in order to decrease the rate of healthcare-associated infections related to that condition or

---

26 For details see http://www.ihi.org/IHI/Topics/CriticalCare/IntensiveCare/ImprovementStories/BundleUpforSafety.htm
that procedure. It is important that bundles are designed, implemented and evaluated with measurement designed for quality improvement rather than research or judgement.

Examples of some procedural care bundles are given in Section B4.

### C1.5.2 Reducing sharps injuries

Safe handling of sharps is discussed in more detail in Section B1.3. A systems approach can support reducing sharps injuries by addressing (CDC 2008):

- **clinical governance**—championing a culture of safety underpinned by concepts of patient-centred care
- **staff health and safety**—adopting and evaluating the use of safety engineered devices as alternatives to sharps without safety engineered features, standardising changes to work practices that will reduce risk (e.g. using instruments, rather than fingers, to grasp needles, retract tissue, and load/unload needles) (see Section C2)
- **education and training**—providing education in the use of new devices and work practices (see Section C3)
- **surveillance**—ensuring comprehensive reporting of injuries and preventive strategies
- **facility design**—applying engineering controls (e.g. sharps disposal containers and sharps devices with integrated engineered sharps injury prevention features).

### C1.5.3 Lowering the incidence of IVD-related bloodstream infections

Section B4.2 outlines infection prevention and control guidance for healthcare workers to follow when inserting a therapeutic device such as a central venous catheter. A range of measures is required for safe use of devices, the first consideration being whether the device is necessary or if a safer alternative could be used.

Facility management and the infection prevention and control team have a key role in working with clinical staff to improve the safety of procedures such as IVD insertion, by providing the necessary support and infrastructure.

The care bundle (see also Section B4.1) for central venous catheter insertion stipulates the use of hand hygiene, maximal barrier protection, optimal intravascular catheter site selection, topical chlorhexidine for skin disinfection, and daily review to ensure that catheters are removed as soon as they are no longer necessary. Support and infrastructure requirements to facilitate implementation of these measures include:

- **clinical governance**—championing a culture of safety underpinned by concepts of patient-centred care
- **education and training**:
  - orientation programs for staff including rigorous grounding in facility policies and procedures for standard procedures, particularly hand hygiene
  - development and promotion of a supporting education program that addresses IVD-associated BSI
  - engagement of patients, so they have the knowledge and skills to be actively involved in their own care.
- **surveillance**:
  - implementation of a tool to quantify adherence to practice (e.g. checklists)
  - measurement of bloodstream infection rates with feedback to relevant staff.
- **facility design and equipment**—provision of appropriate equipment, such as IVD-insertion kits with standardised contents to enable a competent health professional to perform the procedures and adhere to accepted techniques.
C2 Staff health and safety

Summary

• Infection protection for healthcare workers should be an integral part of the infection prevention and control and occupational health and safety programs of every healthcare facility.
• This includes implementing a staff health screening policy, promoting immunisation, instituting extra protection for healthcare workers in specific circumstances (e.g. pregnant healthcare workers), and having processes for minimising and managing risk exposure.
• While the organisation has a duty of care to healthcare workers, staff members also have a responsibility to protect themselves and to not put others at risk.

C2.1 Roles and responsibilities

In the course of their duties, healthcare workers can be exposed to infectious agents (e.g. through direct contact with an infectious patient, visitor or colleague or indirectly through a contaminated surface or environment [i.e. air] or as the result of a sharps injury). Healthcare workers can also place patients at risk of transmission of infection (e.g. if the healthcare worker has an infectious condition that is capable of being transmitted as they perform their duties).

To ensure the safety of everyone in the facility, both employers and employees have a responsibility in relation to infection prevention and control and occupational health and safety.

C2.1.1 Responsibilities of healthcare facilities

Workplace Health and Safety Acts for the various states and territories place a duty of care on employers to ensure workplace health and safety, including where occupational infectious disease hazards exist.

As part of its IPC program, each healthcare facility should develop, implement and document effective policies and procedures related to staff health and safety, including strategies to prevent occupational exposure to infection hazards; prevent occupational risks from chemicals or processes used for recommended infection prevention and control activities; and implement healthcare worker immunisation programs for infectious agents they may encounter in the course of their duties.

At the start of their employment, all healthcare workers should be informed of the facility’s policy on health screening and be counselled, as appropriate, about their work placement in accordance with these policies. As personal and organisational circumstances change over time, reassessment and additional education may be necessary. Similarly, training institutions should inform healthcare students before their course admission about policies and procedures for staff health and safety and their implications, and provide counselling for students who may be prohibited from completing any requirements of their course due to transmissible infections.

Healthcare worker's privacy and civil rights must always be respected and not breached.
Positive measures should be undertaken to implement and sustain appropriate infection prevention and control. There are five measures of protection:

- health status screening (see Section C2.2.1)
- education on safe work practices that minimise the transmission of infection (see Section C3)
- safe systems of work, with workplaces designed to allow clinical practice that minimises transmission of infection (see Section B4)
- physical protection, involving the use of PPE (see Section B.1.2) and immunisation (Section C2.2.2)
- reporting systems for compliance and identifying breaches of infection prevention and control protocols.

C2.1.2 Responsibilities of healthcare workers

Healthcare workers have an obligation to always follow specific established infection prevention and control policies as part of their contract of employment. This includes reporting their infectious status if it places others at risk as well as any known potential exposures to blood and/or body substances. Failure to follow infection prevention and control policies and procedures may be grounds for disciplinary action. Some states/territories have statutory infection prevention and control requirements for healthcare workers.

Healthcare workers with infections should seek appropriate medical care from a doctor qualified to manage their condition. Where there is a risk of a healthcare worker transmitting infection to a patient or other healthcare worker (e.g. if he or she is infected with an acute or other transmissible infection, carries a blood borne virus, or has a predisposing skin condition), the healthcare worker should be counselled about work options and either rostered appropriately or provided with equipment, information and facilities to enable him or her to perform their duties without placing others at risk.

The appropriate work option will depend on the specific circumstances:

- healthcare workers with symptoms of acute infections (e.g. vomiting, diarrhoea, flu symptoms) should not come to work for the specified exclusion period (see Section C2.3)
- healthcare workers who carry a bloodborne virus (e.g. hepatitis B, hepatitis C, HIV) may need to accept that their duties may be modified if they perform exposure-prone procedures that pose a potential risk to patients and other staff. In some jurisdictions, healthcare workers who carry a bloodborne virus are legally obliged to declare their infectious status.

Healthcare workers should be aware of their requirements for immunisation against infectious diseases and maintain personal immunisation records.

Healthcare workers in specific circumstances (e.g. pregnant healthcare workers) may be particularly susceptible to some infections and should work with occupational health and safety officers to ensure their safety (see Section C2.4).

Education about safe work practices is discussed in Section C3.
C2.2 Health status screening and immunisation

C2.2.1 Staff health screening policies

Before beginning employment, all staff should be assessed and offered testing and/or vaccination for specific infectious diseases before being allowed to work in high-risk areas. Particular attention should be paid to immune status, skin conditions and pregnancy in staff, as well as risk factors for specific groups of patients. These conditions may vary according to state/territory specific requirements and recommendations.

Routine screening and assessment

Routine screening at the start of employment occurs in three forms:

• **personal assessment of disease and immune status**—a questionnaire (with recording of information gained) should check for details of medical history, particularly for rubella, measles (rubeola), mumps, chickenpox (varicella), hepatitis B, immune disorders and skin conditions, and for prior exposure to tuberculosis (including working in high-risk settings and high-risk demographic background)

• **immunisation**—(see Section C2.2.2)

• **laboratory and other testing**—this should include a routine tuberculin skin test. Routine screening for patients who are streptococcus carriers is not recommended, although this form of screening may be instituted in the case of an outbreak.

These principles for screening and immunisation also apply to any healthcare students, work experience students and volunteers who are likely to be exposed to potential risks.

Pre-employment screening and immunisation

Pre-employment screening and immunisation requirements for healthcare workers can be determined using a risk classification system that assesses the exposure to blood and body substances. Work activities, rather than job title, must be considered on an individual basis when determining risk categorisation.

All Category A healthcare workers (see Table C2.1) are required to be able to provide evidence of serological immunity or vaccination history. Acceptable evidence of protection includes a written record of vaccination signed by the provider and/or serological confirmation of protection. This does not include a statutory declaration.
### Table C2.1: Determining risk categorisation for pre-employment screening and immunisation

<table>
<thead>
<tr>
<th>Category</th>
<th>Risk</th>
<th>Examples</th>
</tr>
</thead>
</table>
| A        | Direct contact with blood or body substances  
This category includes all persons who have physical contact with, or potential exposure to, blood or body substances                                                   | dentists, medical practitioners, nurses, allied health practitioners, health care students, laboratory staff, maintenance engineers who service equipment, sterilising service staff, cleaners, and staff responsible for the decontamination and disposal of contaminated materials. |
| B        | Indirect contact with blood and body substances  
Rarely have direct contact with blood or body substances. These employees may be exposed to infections spread by the airborne or droplet routes, but are unlikely to be at occupational risk from blood borne diseases. | catering staff and ward clerks                                                                                                                                                                           |
| C        | Minimal patient contact  
Occupational groups that have no greater exposure to infectious diseases than do the general public. The exact nature of job responsibilities should be taken into account when deciding immunisation requirements, and all staff should be encouraged to be fully vaccinated. | office clerical staff, gardening staff and kitchen staff                                                                                                                                         |
<p>| Laboratory staff | May have additional vaccination requirements if they are working with or may be exposed to specific agents, e.g. Q Fever, anthrax, poliomyelitis, Japanese encephalitis |                                                                                                                                                                                                              |</p>

<td>To be considered for healthcare workers with patient contact</td>
</tr>
</tbody>
</table>

**C2.2.2 Immunisation**

Employers should take all reasonable steps to ensure that staff members are protected against vaccine-preventable diseases. Where healthcare workers may be at significant occupational risk of acquiring or transmitting a vaccine-preventable disease, a comprehensive occupational vaccination program should be implemented. Such a program should include:

- a vaccination policy
- maintenance of current staff vaccination records
- provision of information about the relevant vaccine-preventable diseases
- the management of vaccine refusal (which should, for example, include reducing the risk of a healthcare worker transmitting disease to a vulnerable patient).

Healthcare facilities should advise healthcare workers of the potential consequences if they refuse...
reasonable requests for immunisation. Such advice and refusal to comply should be documented.
Duties may be modified if healthcare workers have a confirmed infection that may directly affect
the risk of transmission of infection during exposure-prone procedures. This is determined at the
local facility level.

Vaccine refusal, contraindication to vaccination and vaccine non-response may be managed
by ensuring appropriate work placements, work adjustments and work restrictions.

**Recommended vaccinations**

The most recent edition of *The Australian Immunisation Handbook* (currently NHMRC 2008)
provides detailed information on immunisation schedules and vaccines. Staff vaccination
programs should comply as much as possible with these schedules, which acknowledge that
some circumstances may require special consideration before vaccination.

**Pre-vaccination screening**

Pre-vaccination screening is outlined in Section 1.3.4 of the *Australian Immunisation Handbook*,
including a pre-vaccination checklist. Healthcare facilities should have education programs to
support their immunisation policy and reinforce the need for compliance.

**C2.2.3 Staff records**

Employers and healthcare facilities need to retain details of screening results and immunisations provided, including vaccine preventable disease history, date and results of serology, record of immunisations consented/ refused, date given and batch number, type and brand name of vaccine.

Records need to be secure and accessible by authorised personnel when needed, updated when relevant events occur, and maintained in accordance with confidentiality and privacy laws.

---

C2.3 Exclusion periods for healthcare workers with acute infections

Every healthcare facility should have comprehensive written policies regarding disease-specific work restriction and exclusion, which include a statement of authority defining who can implement such policies.

Any employee who has an infectious disease has a responsibility to:

- consult with an appropriate medical practitioner to determine that they are capable of performing their tasks without putting patients or other workers at risk
- undergo regular medical follow-up and comply with all aspects of informed clinical management regarding their condition.

These policies should encourage healthcare workers to seek appropriate preventive and curative care and report their illnesses, medical conditions, or treatments that can render them more susceptible to opportunistic infection or exposures. They should not penalise healthcare workers with loss of wages, benefits, or job status.

The overarching principle for exclusion periods is that staff members should not come to work if they have signs or symptoms of a potentially infectious disease.

<table>
<thead>
<tr>
<th>Acute infection</th>
<th>Exclusion period</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conjunctivitis</td>
<td>Must not provide patient care for the duration of symptoms (i.e. while eye discharge is present).</td>
</tr>
<tr>
<td>Gastroenteritis* (except norovirus)</td>
<td>Must not come to work while symptomatic (e.g. diarrhoea and/or vomiting) and until 24 hours after symptoms have resolved</td>
</tr>
<tr>
<td>Glandular fever</td>
<td>NO need for exclusion, even if having direct patient contact, provided staff members are well enough to return to work and employ standard precautions.</td>
</tr>
<tr>
<td>Herpes Simplex (cold sores)</td>
<td>Must not provide direct care to neonates, newborns, patients in delivery suites, severely immunocompromised patients, burns patients, patients with extensive eczema, or patients in operating room if there is an exposed herpetic lesion. May provide direct patient care to other patients, do not need to wear a mask.</td>
</tr>
<tr>
<td>Herpes Zoster (Shingles)</td>
<td>Must not provide ANY direct patient care if lesions cannot be covered (e.g. ophthalmic zoster). If active lesions can be covered, can provide care to all patients except for pregnant women, neonates, severely immunocompromised patients, burns patients and patients with extensive eczema.</td>
</tr>
<tr>
<td>Influenza</td>
<td>Employees should remain off work for 5–6 days or until they are symptom free.</td>
</tr>
<tr>
<td>Norovirus</td>
<td>Must not come to work while symptomatic (e.g. diarrhoea and/or vomiting) and until 48 hours after symptoms have resolved (see GPP below).</td>
</tr>
<tr>
<td>Pertussis (Whooping Cough)</td>
<td>Remain away from work until at least 5 days after commencement of appropriate antibiotic therapy, or for 21 days after the onset of symptoms if not receiving antibiotic treatment.</td>
</tr>
<tr>
<td>Scabies and Lice</td>
<td>Remain off work until 1st treatment has been completed.</td>
</tr>
<tr>
<td>Staphylococcal infection</td>
<td>Any staphylococcal lesions (e.g. boils, wound infections) must be covered with an occlusive dressing while at work. If lesions cannot be covered, must not perform patient care or prepare hospital food until they have received appropriate antibiotic therapy and the infection has resolved.</td>
</tr>
</tbody>
</table>
### Acute infection | Exclusion period
--- | ---
**Streptococcal infection** | Any employee with streptococcal lesions (e.g. impetigo, tonsillitis) must ensure that lesions are covered with an occlusive dressing while at work. If lesions cannot be covered, employees must not provide direct patient care nor prepare hospital food until 24 hours after commencement of appropriate antibiotic therapy. Employees with pharyngitis/tonsillitis should avoid patient contact for at least 24 hours after starting appropriate antibiotic therapy.

**Tuberculosis (TB)** | If TB disease is suspected or is present, staff to be notified to TB Services and treated. Any personnel with pulmonary TB is to be excluded from the workplace until cleared by TB Services. Any active TB must be monitored by TB Services.

**Viral rashes** | Measles (Rubeola)—If suspected, must remain off of work until appropriate test results are known. May return to work if they have serological evidence of immunity (i.e. are IgG sero-positive and IgM sero-negative); but must be excluded until 4 days after the appearance of the rash if they develop measles.

Mumps—If suspected, must remain off work until appropriate test results are known. May return to work if they have serological evidence of immunity (i.e. are IgG sero-positive and IgM sero-negative). Must be excluded from work for 9 days after the onset of parotid gland swelling if they develop mumps.

Rubella (German Measles)—If suspected, must remain off work until appropriate test results are known. May return to work if they have serological evidence of immunity (i.e. are IgG sero-positive and IgM sero-negative). Personnel must be excluded for 4 days after the appearance of the rash if they develop Rubella.

Chickenpox (Varicella)—Before starting employment, personnel should be screened by completing a pre-employment health assessment; non immune staff should be offered vaccination unless contraindicated; personnel must be until all blisters have dried.

Human Parvovirus B19 (Slapped Face)—does not require exclusion from work, non-infectious once rash develops.

**Viral respiratory tract infections** (e.g. common cold) | Staff should be excluded from contact with susceptible persons, until they are no longer symptomatic. Staff with viral respiratory tract infections should stay at home until they feel well.

---

* Includes giardiasis, *Shigella* infection, *Salmonella* infection, *Campylobacter* infection

**Source:** Adapted from Staying Healthy in Child Care - Preventing infectious diseases in child care - Fourth Edition

---

**Good practice point**

**Norovirus exclusion periods**

Healthcare workers should not return to work until diarrhoea and vomiting have ceased for 2 days.

It is extremely important that healthcare workers comply with appropriate hand hygiene methods and stringent infection prevention and control practices upon return to work, as some studies have shown prolonged viral shedding with this infection.
C2.4 Healthcare workers with specific circumstances

Healthcare facilities need to assist healthcare workers experiencing circumstances that place them at greater risk of infection to develop management plans that ensure their well-being.

Where a healthcare worker is known to be particularly susceptible to healthcare associated infections, work duties are assessed to ensure that the welfare of that person, patients and other healthcare workers is safeguarded. This may involve appropriate work placements, adjustments or restrictions, or deployment to a role involving less risk. Healthcare workers in this situation may require counselling on what tasks they can perform, what they should avoid and the possible impact of their work on their health.

C2.4.1 Pregnant healthcare workers

Employers should provide information on the risks associated with pregnancy and should assist pregnant healthcare workers to avoid infectious circumstances that may present a risk to her or the baby. It is the responsibility of pregnant healthcare workers to advise their doctor and employer of their pregnancy; this information must remain confidential.

All pregnant healthcare workers should adhere to standard and transmission-based precautions and ensure that they are appropriately vaccinated. However, pregnant healthcare workers should be given the opportunity to avoid patients with specific infections.

For more information, refer to Section 2.3.2 of the Australian Immunisation Handbook.

C2.4.2 Immunocompromised healthcare workers

Healthcare workers with immune deficiencies are more at risk of acquiring infections. The type of employment they can undertake should include only duties that will minimise their exposure to infections. Predisposing conditions include neutropenia, disseminated malignancy and infections that produce immunodeficiency (e.g. HIV).

Refer to Section 2.3.3 of the Australian Immunisation Handbook for guidance on the immunisation of immunocompromised healthcare workers.

C2.4.3 Healthcare workers with skin conditions

Skin integrity is the ultimate barrier to transmission of infectious agents. When staff members have damaged skin or weeping skin conditions (e.g. allergic eczema, psoriasis, exfoliating dermatitis), they may be readily colonised by healthcare associated microorganisms and may become a vehicle for disseminating these organisms. Healthcare workers in this situation should be identified by personal history screening when they start employment, and need to be informed of the risks they may pose to patients. Any damaged skin must be appropriately covered before healthcare workers carry out procedures. Consideration must be given to providing these staff members with appropriate, individual PPE such as specific types of gloves, hand hygiene product and moisturising lotion.

C2.5 Exposure-prone procedures

Exposure prone procedures (EPPs) are invasive procedures where there is potential for direct contact between the skin, usually finger or thumb of the healthcare worker, and sharp surgical instruments, needles, or sharp body parts (e.g. fractured bones), spicules of bone or teeth in body cavities or in poorly visualised or confined body sites, including the mouth of the patient.
During EPPs, there is an increased risk of transmitting bloodborne viruses between healthcare workers and patients. A list of EPPs is in Section B5.3. The nature of EPPs can be categorised according to level of risk of transmission, in increasing order of magnitude.

### Table C3: Categories of exposure prone procedures

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Category 1</strong></td>
<td>A procedure where the hands and fingertips of the healthcare worker are usually visible and outside the body most of the time and the possibility of injury to the worker’s gloved hands from sharp instruments and/or tissues is slight. This means that the risk of the healthcare worker bleeding into a patient’s open tissues should be remote (e.g. insertion of a chest drain).</td>
</tr>
<tr>
<td><strong>Category 2</strong></td>
<td>A procedure where the fingertips may not be visible at all times but injury to the healthcare worker’s gloved hands from sharp instruments and/or tissues is unlikely. If injury occurs it is likely to be noticed and acted upon quickly to avoid the healthcare worker’s blood contaminating a patient’s open tissues (e.g. appendectomy).</td>
</tr>
<tr>
<td><strong>Category 3</strong></td>
<td>A procedure where the fingertips are out of sight for a significant part of the procedure, or during certain critical stages, and in which there is a distinct risk of injury to the healthcare worker’s gloved hands from sharp instruments and/or tissues. In such circumstances it is possible that exposure of the patient’s open tissues to the healthcare worker’s blood may go unnoticed or would not be noticed immediately (e.g. hysterectomy).</td>
</tr>
</tbody>
</table>

### C2.5.1 Responsibilities

**Employers**

Employers must ensure that employees who perform EPPs have access to appropriate information, testing, training, counselling and vaccination programs. Serological testing may be provided by the healthcare facility or healthcare workers may choose to seek testing from outside sources. Healthcare facilities should aim to achieve voluntary compliance and self-disclosure by providing an environment in which healthcare workers know their confidentiality will be maintained.

Under current notification requirements, medical practitioners or laboratories must notify the chief medical officer or state/territory health department of cases of HIV, HBV and HCV, by either name or code.

A medical practitioner may be legally obliged to bring to the attention of the appropriate registration board any registered professional who is unable to practise competently or who poses a threat to public safety.

Healthcare workers who need to modify their work practices because they are carriers of a bloodborne virus should be provided with counselling and, where practical, with opportunities to continue appropriate patient-care activities, either in their current position or in a redeployed position, or to obtain alternative career training.

**Healthcare workers**

Healthcare workers who undertake EPPs have a responsibility to know their infectious status with regard to bloodborne viruses such as hepatitis B virus, hepatitis C virus and HIV, and should be given relevant information about the tests available and encouraged to have voluntary testing.
Healthcare workers who carry a bloodborne virus have a clear responsibility to follow the treatment recommended by their doctor and modify their involvement in direct patient care. They must not perform EPPs if they are:

- HIV antibody positive
- hepatitis B e antigen (HBeAg) positive and/or hepatitis B DNA positive at high titres
- hepatitis C RNA positive (by nucleic acid test).

Healthcare workers who carry a bloodborne virus and are not in these categories must not perform EPPs until specialist medical advice has been sought.

Healthcare workers who are currently hepatitis B surface antigen (HBsAg) positive and hepatitis B DNA negative or hepatitis C antibody positive and hepatitis C RNA negative must obtain ongoing medical advice regarding their potential infectiousness and the appropriateness of their continued performance of EPPs.

Healthcare students

Conditional registration may be required for students who have had to undertake modified training programs. This will require an undertaking that individuals who are known to carry HIV, HCV or HBV will report their infectious status at the start of their training and agree not to perform EPPs. Training courses that require the performance of EPPs should include information, counselling, opportunities for testing and career advice.

Training institutions should counsel student healthcare workers carrying bloodborne illness capable of being transmitted through EPPs, against a career in any profession that may involve such procedures.

C2.6 Occupational hazards for healthcare workers

Needlestick and other blood or body substance incidents are the main causes of occupational hazards for healthcare workers, including HIV, HBV and HCV.

C2.6.1 Sharps injuries

Healthcare workers face the risk of injury from needles and other sharp instruments during many routine procedures. Injuries most often occur after use and before disposal of a sharp device, during use of a sharp device on a patient and during disposal (CDC 2009). There are many possible mechanisms of injury during each of these periods.

Measures to help combat needlestick and other sharps injuries include: training and education on the risks associated with procedures and on the use of needlestick devices; and safer working practices (including adherence to proper handling and disposal procedures and ensuring that disposal containers are not overfilled [see also Section C1.5.1]).

The use of devices with safety engineered protective features was mandated in the US in 2000 and has been associated with reduced rates of incidence of needlestick injuries (Jagger et al 2008). Despite difficulties in determining the direct impact of using safety-engineered devices compared to standard devices, safety-engineered devices are an important component in percutaneous injury prevention (Tuma & Sepkowitz 2006). Typically a sharps-injury campaign involves multi-modal strategies. As a result many studies that show a reduction in incidence of needlestick injuries

28 Communicable Disease Network Australia Guidelines for Managing Blood-Borne Virus Infection in Health Care Workers 2005, which are currently under review.

29 Previously published guidelines have stated that HCWs must not perform EPPs if they are HBeAg positive and/or hepatitis B DNA positive at high titres. Whether HCWs with any level of hepatitis B DNA should perform EPPs is under review by Australian infectious disease experts. When there is a nationally agreed approach this Guideline will be updated, but in the meantime, HCWs wishing to perform EPPs who are hepatitis B DNA positive should consult their local health authority for advice.
with the use of safety engineered devices have also involved a combination of other intervention measures such as training and education, overarching healthcare facility policies and other technologies (Whitby et al 2008).

Australia is the only country with well-developed systems of infection prevention and control and occupational health and safety that has not yet mandated the use of safety or retractable devices. Such mandates exist in the USA, Canada and most recently the European Union, including the UK. The current UK policy recommends the provision of medical devices that incorporate a sharps protection mechanism where there are clear indications that they will provide safe systems of working for healthcare workers. Consideration of economic and social costs, staff preferences, ease of use, and time required to train staff is necessary before widespread implementation of safety-engineered devices in Australia. In the meantime, if a facility chooses to use safety-engineered devices, introduction of the devices must be supported by a comprehensive training and education program.

C2.6.2 Managing risk of exposure

Exposures that might place a healthcare worker at risk of hepatitis B virus, hepatitis C virus, HIV or human T-cell lymphotropic virus type I (HTLV-I) are percutaneous injury (e.g. needlestick or cut with a sharp object) or contact of mucous membrane or non-intact skin (e.g. exposed skin that is chapped, abraded, or affected by dermatitis) with blood, tissue or other potentially infectious body substances.

Each healthcare facility requires a policy on the management of needlestick injuries, and on providing immediate post-exposure advice for sharps injuries and other blood or body substance incidents involving healthcare workers, as generic policies may not be relevant to individual settings (e.g. access to care, especially after hours).

Treatment protocols include removal of contaminated clothing, thorough washing of the injured area with soap and water; and flushing of affected mucous membranes with large amounts of water.

Healthcare workers should be aware that they must report occupational exposures immediately.

Post-exposure prophylaxis

Post-exposure prophylaxis (PEP) is the medical response given to prevent the transmission of bloodborne pathogens following a potential exposure. PEP includes first aid, counselling including the assessment of risk of exposure to the infection, testing, and depending on the outcome of the exposure assessment, the prescription of antiretroviral drugs, with appropriate support and follow-up (WHO 2008).

• For people who have an exposure to a known source, post exposure prophylaxis (PEP) should be offered for HIV as soon as possible after the incident. Initiation of HIV PEP depends on the type of exposure, the source's stage of HIV infection, the source's HIV viral load and the source's history of HIV antiretroviral therapy. Therefore, a thorough assessment of risk guides the actions to be taken.

• Initiation of HBV PEP is dependent on the type of exposure, the source's HBsAg status and the exposed persons HBV immunisation history.

• At this time, there is no prophylaxis proven to be effective for Hepatitis C. The aim of follow up is to detect acute hepatitis C as soon as possible so that appropriate management can be instituted.

Standard guidelines for pre-test counselling or pre-test discussions for HIV, HBV and HCV must be followed when testing the source and the healthcare worker.

Specific guidance on PEP can be found in WHO guidelines (WHO 2008) and CDC (2005). The ASHM guidelines are relevant to non-occupational exposure but include references to jurisdictional guidelines for occupational exposure (see Section C7 for links).
C3  Education and training

Summary

- Education and training underpin efforts to integrate infection prevention and control practices into practice at all levels of every healthcare facility.
- Essential education for all healthcare workers should cover infection prevention and control work practices and their role in preventing the spread of infection, as part of undergraduate education, staff orientation and continuing professional development.
- Specific postgraduate education of infection control professionals is strongly recommended.
- Engaging patients, their carers and families in their own healthcare is integral to effective infection prevention and control. All healthcare workers should be informed about the rights and responsibilities of patients and learn how to apply this understanding in the way that they deliver care.

C3.1  Universities and training colleges

All healthcare workers need to understand the basis and importance of infection prevention and control. Up-to-date information on infection prevention and control basics, policy, procedures, quality assurance and incident monitoring should be included in the curriculum of all undergraduate and postgraduate courses in health-related areas.

Universities and training colleges also have an obligation to inform prospective students about the impact that particular infections may have on their ability to complete the course and engage in the full spectrum of clinical practice after graduation (see Section C2). This information should include advice about specific measures, including immunisation, that reduce the risk of acquiring infection.

C3.1.1  Education of infection control professionals

While some states in Australia have requirements for practising as an infection control professional, there is currently no minimum or standardised educational requirement to practice as an infection control professional, or to coordinate an organisational IPC program. A range of postgraduate education programs are currently available for nurses seeking or establishing a career in infection control in Australia, although the content of these courses is variable.

Good practice point

Education of infection control professionals

Postgraduate education gives infection control professionals the necessary expertise to fulfil the role. Specific professional development should be supported at all levels.
Case study—Requirements for infection control professionals in Tasmania

Senior infection control professionals (e.g. at Clinical Nurse Consultant or Clinical Nurse Manager level) must have adequate skills including:

- formal post graduate qualifications at a Diploma level and working towards a Masters degree or higher in an area relevant to infection prevention and control
- being a credentialled infection control professional (AICA or CBIC)
- participation in professional development opportunities including attendance at relevant state and/or national professional organisation meetings in accordance with Award conditions.

Infection control professionals at clinical nurse or clinical nurse specialist level must:

- have formal postgraduate qualifications at a Certificate level or higher in an area relevant to infection prevention and control
- have regular access to professional and clinical support
- participate in professional development opportunities
- be credentialled (AICA or CBIC).

C3.2 Healthcare worker education

Healthcare facilities should provide specific education and training for all healthcare workers and students about infection prevention and control principles, policies and procedures that are relevant to the facility. The aim is to inform and educate healthcare workers about the infectious hazards they will face during their employment, and their role in minimising the spread of infection to others. Special attention should be given to advice about hand hygiene (see Section C3.4). The role of clinical educators in providing this education needs to be supported, as they provide a vital link between teaching and healthcare facilities.

At a minimum, all staff (both clinical and non clinical) should be educated about:

- modes of transmission of infectious agents
- risk identification, assessment and management strategies including transmission-based precautions
- orientation to the physical work environment with a focus on its risks for infection
- safe work procedures
- correct use of standard precautions
- correct choice and use of PPE, including procedures for putting on and removing PPE and fit checking of respirators
- appropriate attire (shoes/hair/nails/jewellery)
- hand hygiene practices (see case study in Section C3.4)
- levels of cleaning required for clinical areas and equipment
- how to deal with spills
- safe handling and disposal of sharps
- reporting requirements of incidents such as sharps injuries and exposures
- waste management
- antibiotic policy and practice.

---

30 As outlined in the Tasmanian Healthcare Associated Infection Prevention Strategy 2009–11
This information should be provided in the context of their roles in the organisation or practice, and with a focus on respecting and maintaining patient confidentiality at all times. It should be provided as part of their orientation, with periodic updates and refresher courses as required for their specific jobs.

Healthcare workers may also require job or task-specific education and training, such as:

- instrument cleaning and sterilisation competency testing
- insertion and management of central and peripheral lines
- risks and prevention of MRO transmission.

Job-specific training should be provided as part of orientation, when new procedures affect the employee's occupational exposure, before rostering to hazardous areas (e.g. caring for patients on airborne precautions in a negative pressure room); and at a minimum, in annual refresher courses. Healthcare workers should be assessed to ensure that they are competent in using and consistently adhering to the specific infection prevention and control practice. Healthcare facilities should maintain records of participation by healthcare workers in infection prevention and control education programs.

### C3.3 Education strategies

The term 'educational strategies' encompasses a wide range of commonly applied interventions that aim to bring about and sustain changes in the practice of healthcare workers. A review was undertaken to inform the development of these guidelines, identifying relevant systematic reviews of educational interventions in general healthcare settings and, more specifically, where education has been used to reduce healthcare associated infections and improve hand hygiene in the workplace.

Examples of education activities include:

- educational meetings, either didactic (e.g. lecture, presentation) or interactive (e.g. workshop with role play and case discussion)
- educational materials, either printed or audiovisual
- educational outreach, where an intervention is delivered by a visiting infection prevention and control expert
- continuing medical education
- multifaceted, tailored interventions to address barriers to good practice
- inter-professional education.

While the overall findings of the reviews were inconclusive, they did identify some consistent trends:

- Multifaceted strategies, which consider the needs of the target group, potential barriers and facilitators and the context in which educational strategies are applied, are likely to be more effective than single strategies, although it is not known what combination of interventions, if any, is optimal.
- Active educational interventions that are repeated with some frequency have a greater chance of changing behaviour than a single, didactic session. Repetition and interactivity have both been shown to be important factors in achieving behaviour change that is sustained.
- The distribution of printed materials on their own was not found to be consistently effective, but may contribute when included in a multifaceted intervention. The use of multiple forms of media in an education intervention may be more effective than the use of single media.
- Educational outreach visits have been found to be an effective method, especially when combined with other strategies such as interactive education and printed materials, but are costly to implement. They seem to be most effective when related to prescribing practices of moderate complexity.

Education activities can be integrated into staff orientation programs, credentialling packages,
annual training and competency testing, implementation of policy and procedure manuals, and in decision support tools available on the facility intranet. The infection control professionals’ contact details should be readily available to all staff and included in all resources.

E-learning (e.g. interactive web-based training) is being used in some states, and may be a useful addition to other education strategies. For example, the Queensland Health Clinician Development Education Service offers interactive flexible on-line learning programs across a wide range of topics, including infection prevention and control, which are available 24 hours a day from work or home.

**C3.4 Example of education in practice—hand hygiene**

Hand hygiene is the most important of the infection prevention and control strategies. According to the *Hand Hygiene Australia Manual*, healthcare workers must perform hand hygiene before and after every patient contact to prevent patients becoming colonised with pathogens from other patients and the healthcare facility environment. Emphasis must also be placed on preventing the transfer of organisms from a contaminated body site to a clean body site during patient care. The latest guidelines also recommend hand hygiene after contact with inanimate objects, including medical charts and equipment in the immediate vicinity of the patient.

Hand hygiene is a good example of the role of education in efforts to improve infection prevention and control practice. Although the concept of hand hygiene is straightforward, improving hand hygiene practices involves changing attitudes and behaviour among healthcare workers. Numerous barriers to appropriate hand hygiene have been reported, several of which reflect lack of understanding and knowledge (Grayson et al 2009):

- all hand hygiene agents being thought to cause skin irritation and dryness
- patient needs being perceived to take priority over hand hygiene
- perception that glove use dispenses with the need for additional hand hygiene
- belief that there is insufficient time for hand hygiene, due to high workload
- inadequate knowledge of guidelines or protocols for hand hygiene
- lack of role models
- lack of recognition of the risk of cross-transmission of microbial pathogens.

As discussed in Section B1.1, the use of alcohol-based hand rub, coupled with changes in the recommended indications for hand hygiene and a change in attitudes and behaviour of healthcare workers provides the best approach to preventing HCAI transmission.

**C3.4.1 National Hand Hygiene Initiative**

Recent hand hygiene programs in Victorian hospitals have led to significantly increased compliance with hand hygiene (Grayson et al 2008; Johnson et al 2005). These were comprehensive culture-change programs involving widespread availability of alcohol-based hand rubs in clinical areas and targeted education of healthcare workers.
The National Hand Hygiene Initiative (NHHI) coordinated by ACSQHC is based on the above studies and the WHO ‘5 moments’ program. It aims to implement a national approach to improving hand hygiene and monitoring its effectiveness. In the initiative, healthcare worker education is a key component of a multi-modal intervention strategy, involving basic educational sessions for all healthcare workers, including:

- definition, impact and burden of HAI
- common pathways for disease transmission, specifically the role of hands
- prevention of HAI and the role of hand hygiene
- 5 Moments for Hand Hygiene – with key messages
- when to perform hand hygiene
- use of alcohol-based hand rubs
- use at point of care.

As well as introductory educational sessions, a program of formal regular sessions and updates is recommended, taking the form of specific orientation programs, in-service lectures or special workshops. All education sessions are supported by an online training package, DVD, video demonstrations of each of the five moments, and slide presentations.

Other opportunities for education include:

- informal education opportunities in day-to-day activities such as nursing ward rounds, clinical unit meetings, increased presence on the ward by infection prevention and control staff, and prompt feedback of compliance results
- promotional activities to raise awareness, with promotional products (e.g. stickers) or incentives for staff who attend education sessions.

For healthcare workers, a multi-modal approach is also recommended, led by hand hygiene champions who encourage all staff to act as role models for others. Other opportunities include regular scientific presentations at surgical and medical meetings, including Grand Rounds, and regular attendance by infection prevention and control staff at medical ward rounds. All healthcare workers should be regularly assessed for their hand hygiene compliance and be provided with rapid feedback of results (see 3.5.1).

Other measures to increase compliance with hand hygiene are discussed in Section C6.

**C3.5 Patient engagement**

Informing patients and carers about infection prevention strategies and taking their experience and feedback into account are pivotal to safe and effective clinical care. Patient engagement is not just about giving information, it is a process of informing, listening and interacting that gives patients the skills and knowledge to be actively involved in their own health care, give feedback and participate in quality improvement activities.

Through open, respectful interactions with healthcare workers, patients and carers can be given information and support to ensure that they are able to maintain a safe environment in which they receive their care (e.g. information on caring for wounds, basic advice on hand hygiene and spread of infection).
Written material (such as brochures and posters) can be used to reinforce verbal discussions with patients as part of their care. Examples of useful instructional materials for patients and visitors include:

- recommended hand hygiene
- respiratory hygiene and cough etiquette practices
- the need for and application of transmission-based precautions
- information about specific MROs (e.g. MRSA or C. difficile) and how to stop them spreading.

Patient engagement is especially important in the event of a gastroenteritis or influenza outbreak or entry into a ward that houses immunosuppressed patients.

C3.6 Compliance and accreditation

C3.6.1 Auditing

Auditing of healthcare worker behaviour is important for surveillance and accreditation, and to reinforce positive signs of culture change within the facility. Auditing to measure compliance with infection prevention and control policies and procedures can occur through:

- direct observation
- examining logs and registers of specific activities (e.g. sterilisers)
- monitoring use of PPE or hand hygiene products.

Timely feedback is a critical aspect of auditing. In acute-care settings, measurement and feedback generally occurs at ward level.

C3.6.2 Accreditation and credentialing

AICA (Australian Infection Control Association), the peak national body representing the interests of the specialist practice of infection prevention and control within Australia, recommends certificated credentialing of infection control professionals. This is a self-regulatory process to determine and acknowledge that an individual has demonstrated prescribed competence of the relevant specialist nursing role.

C3.6.3 Mentoring, support and networking

While there are no formal mentoring programs in place, many infection control professionals provide mentoring to less experienced staff. Mentoring requires the support of health facility administrators, so that it is recognised as being part of healthcare worker core time, but additional to their workload. Mentoring can also take place more broadly, as illustrated in this case study.

Mentoring of infection control professionals in Tasmania

The Tasmanian Infection Prevention and Control Unit established a forum for infection control professionals to get together every two months. All infection control professionals working in acute hospitals are encouraged to join in via video conference. Each forum, three to four infection prevention and control related research papers are presented and discussed. Each infection control professional is expected to present one paper in a 12-month period. Included in the forum is discussion around current issues faced or new developments in the world of infection prevention and control.

There are networking and support forums available through AICA and the AICA state and territory affiliated associations, as well as region-based forums, and infection control professionals can also use other informal networks and contacts with other infection control professionals.
C4 Healthcare-associated infection surveillance

Summary

• Appropriate surveillance can substantially reduce healthcare-associated infections, morbidity and mortality.
• Both outcome and process measures are used for surveillance in large health facilities; process measures alone can provide a useful alternative, particularly in smaller facilities.
• Timely targeted feedback is critical for effective surveillance.

Many infections can be prevented using approaches based on quality and safety theories such as:
• quality improvement methodologies
• creating a safety culture (individuals taking responsibility for ensuring safety and quality of themselves and others)
• application of systems thinking (i.e. understanding the factors in the system that allow errors to occur).

To be successful, all these approaches need to be based on comprehensive information obtained through surveillance—‘the ongoing, systematic collection, analysis, interpretation, and dissemination of data regarding a health-related event for use in public health action to reduce morbidity and mortality and to improve health’ (CDC 2001).

All healthcare facilities require healthcare-associated infection surveillance systems—local data collection that results in timely feedback has been shown to reduce infection rates.

C4.1 Role of surveillance in reducing HAI

Surveillance is important for wider systems of quality management, but the main purpose of collecting reliable data is to improve quality within a service or facility. Collecting such data can provide the impetus for change and make it possible to evaluate the effectiveness of an intervention. For example, monitoring both hand hygiene compliance and the rate of bloodstream infections, and disseminating the information within the facility, can improve hand hygiene practices.

Surveillance of healthcare-associated infections draws information about the agent, host, environment and risk factors from a number of data sources:
• provides baseline information on the frequency and type of HAI
• enables breakdowns in infection prevention and control to be identified
• allows for timely investigation and appropriate infection prevention and control measures to be instituted.

There is a surveillance cycle, described as ‘data collection–data analysis and interpretation–data dissemination’ (Rothman et al 1998).

All healthcare facilities, including small acute-care facilities and office practices, should collect data on healthcare-associated infections, infection prevention and control breaches, outbreaks of infectious disease and antibiotic resistance. Post-discharge surveillance by community-based healthcare practices should also be considered.

The surveillance system used by a healthcare facility depends on the type and size of the facility, its case mix, and the resources available.

C4.2 Types of surveillance programs

It is not feasible to conduct facility-wide surveillance for all events; therefore surveillance is often targeted, with a focus on specific events, processes, organisms, medical devices or high-risk patient populations. Healthcare-associated infections surveillance programs may focus on:

- specific sites of infection (e.g. bloodstream, surgical sites)
- specific populations (e.g. neonates, healthcare worker occupational exposure to blood and body substances)
- specific organisms or types of organisms (e.g. MRO, C. difficile, RSV, rotavirus)
- specific locations in the healthcare facility or community (e.g. intensive care unit, neonatal intensive care unit, long-term care facility).

There are two main methods of surveillance—process and outcome. Process measurements are usually easier to measure, less ambiguous and more widely applicable than outcome indicators. Process surveillance may be an adjunct to outcome surveillance; alternatively, it can entirely replace outcome surveillance for practices or locations that have too few adverse outcomes for statistical analysis (e.g. small facilities where the number of patients at risk of infection may be too small to calculate valid infection rates).

C4.2.1 Process surveillance

Process surveillance involves auditing practice against a certain standard, guideline or policy. As no single intervention will prevent any healthcare-associated infection, packages of evidence-based interventions have been developed and are increasingly being used in process surveillance (e.g. care bundles, see also Sections B4 and C1.5).

Process measures that are linked by evidence to important outcomes (McKibben et al 2005):

- do not require risk adjustment
- can predict outcomes
- can easily be acted on because potential improvements are usually the responsibility of the clinical service
- can be captured quickly
- are sensitive because many episodes of inappropriate care do not cause harm.

Examples of published process indicators of high value include:

- aseptic insertion and management of peripheral or central intravascular devices
- healthcare workers’ compliance with hand hygiene and the techniques they used
- perioperative and intraoperative practice such as antibiotic prophylaxis, normothermia, normoglycaemia and appropriate hair removal
- healthcare workers’ uptake of immunisation.

C4.2.2 Outcome surveillance

Outcome surveillance involves measuring adverse events, a proportion of which are preventable. The sensitivity and specificity of event definitions and the reliability of data collection need to be considered when developing methods to detect adverse events. It is important to create a balance between avoiding false positives (specificity) and picking up true positives (sensitivity), given that true positives are rare events in the overall patient population.
Certain outcome measures—for example, the incidence of healthcare-associated MRSA bacteraemia—appear to be reliable and have driven practice change, leading to significant improvements in patient safety.

Outcome surveillance with laboratory-based data is used in the signal events system that was designed by Queensland and is implemented in Queensland and South Australia (see also Section C5.3). However, Australia currently has no system-wide approach to measurement of patient mortality caused by or associated with HAI. These deaths are unlikely to be reported using existing mechanisms such as adverse event reporting systems. Mortality from infection may be seen as ‘anticipated’ even though the occurrence of the infection that led to the death was unanticipated.

A further challenge in measuring patient deaths is differentiating between patients who die with a healthcare-associated infection and those who die from a healthcare-associated infection or suffer serious injury due to a healthcare-associated infection (i.e. attributable injury or death). One new approach is to evaluate such patient deaths to determine whether mortality was unexpected, and then analyse the contributing factors to determine preventable root causes that might be modified in future. In this approach, infection events (usually deaths or BSI) are considered and investigated individually. Although mandated by the UK’s National Health Service, evidence of the value of this approach is lacking.

C4.2.3 Critical incidents

If there has been a breakdown in an infection prevention and control procedure or protocol, a ‘lookback’ investigation may be necessary to identify, trace, recall, counsel and test patients or healthcare workers who may have been exposed to an infection, usually a bloodborne virus.

Lookback investigations must be managed with due regard to ethical and legal considerations. In the event of such an incident (e.g. failure of sterilisation or disinfection), the local public health unit should be advised immediately.32

Monitoring of critical incidents and other sentinel events is an important part of surveillance. Root cause analysis of sentinel events is a structured process for identifying the process and contributing factors, exploring and identifying risk reduction strategies and implementing solutions (see Section C1.4.2).

32 The NHMRC publication Guidelines under Section 95 of the Privacy Act 1988 provides further information on the protection of privacy in relation to the compilation or analysis of statistics for health services management or medical research.
C4.3 Data collection and management

Surveillance involves:
- defining surveyed events precisely
- systematic collection of data
- analysis and interpretation
- communication of findings to relevant people.

The following epidemiologic principles should be applied during healthcare-associated infection surveillance:
- use standardised definitions of infection
- use laboratory-based data (when available)
- collect epidemiologically important variables (e.g. clinical service in hospitals and other large facilities, population-specific risk factors, underlying conditions that predispose to serious adverse outcomes)
- analyse data to identify trends that may indicated increased rates of transmission
- feedback information on trends in the incidence and prevalence of healthcare-associated infections, probable risk factors and prevention strategies and their impact, to the appropriate healthcare workers, administrators, and as required by local and state/territory health authorities.

Surveillance data for quality improvement must be of high quality. The characteristics that qualify data as evidence for action include (Booth 1995):
- representativeness—the data fairly represent the thing measured
- accuracy—the data reflect what is intended to be measured
- precision—the data and the target of measurement correspond closely
- authoritativeness—the data are appropriate for drawing a meaningful conclusion
- clarity—the data are presented in a form that the target audience can understand.

Data of this nature are more likely to arise from surveillance processes:
- that involve all stakeholders in design and implementation
- for which there are agreed organisational objectives, and processes that are relevant to the population served
- that use trained staff to collect and manage data, and that provide them with appropriate information technology support
- that use definitions of surveillance events that are unambiguous, practical, specific and can be validated
- that have reliable and practical methods for detecting events
- for which the processes that determine an outcome are thoroughly understood
- for which appropriate denominators are collected for risk adjustment
- for which reporting links measurement to prevention efforts, and meets the needs of both clinicians and managers.
C4.4 Outbreak surveillance

An outbreak may be defined as the occurrence of infections at a rate greater than that expected within a specific geographical area and over a defined period of time.

Ideally, surveillance systems should facilitate the early detection of outbreaks. Increasingly, microbiological data are being relied on for this purpose, although outbreaks may be detected using other sources such as pharmacy records.

In some instances, the occurrence of an outbreak is obvious, such as in an episode of food poisoning that affects both healthcare workers and patients. It is more usual, however, for the outbreak to have an insidious onset that is not immediately apparent. When an outbreak is detected, the infection prevention and control committee should be informed and an outbreak team formed. Depending on the size and severity of the outbreak, it may be necessary to involve occupational health and safety staff, facility administrators, engineers and public health officials. Details on the steps involved in the management of an outbreak are provided in Section B3.2.

Legislation requires that the relevant public health authority be informed of outbreaks related to notifiable infections. It may also be prudent to involve public health officers at an early stage, if an outbreak is likely to come to the attention of the media.

The principles for investigating outbreaks in healthcare facilities are the same as for community-based outbreaks. There are three basic steps:

- describing the outbreak
- developing a hypothesis
- testing the hypothesis with analytical epidemiology.

The tasks involved in any investigation can be summarised as follows:

- Confirm that an outbreak is occurring.
- Determine the background rate of infection, as a temporal cluster of cases may be due to chance alone.
- Confirm the diagnosis using microbiological methods. If possible, confirm that cases are related by typing methods (which may require reference laboratory facilities).
- Define a case, and count cases. Develop a case definition that may include clinical and laboratory data. Start with a broad definition that can be redefined later. In health care establishments, case definition can be relatively easy, with data available through laboratory records and infection prevention and control surveillance data. Remember that cases may have been discharged from the establishment.
- Describe the data in terms of time, place and person and construct an epidemic curve. In healthcare facilities, age, gender and underlying disease are the most useful ‘person’ attributes to record. The location may suggest risk factors.
- Determine who is at risk of becoming ill.
- Look at changes that may have affected the rate of infection (e.g., new staff, new procedures, new tests, new units and healthcare worker:patient ratios).
- Develop a hypothesis and test it by comparison with the facts.
- Undertake analytical epidemiology, such as a case–control or retrospective cohort study, to test the hypothesis quickly.
• After interim control measures are in place, a larger, more systematic study may be warranted, possibly with a different analytical methodology.
• Evaluate the data and prepare a written report.
• Implement longer-term infection prevention and control measures for the prevention of similar outbreaks.

In the interests of public safety (and because of the threat of litigation), all outbreaks, however minor, should be investigated thoroughly and the outcomes of such investigations documented. All institutions should therefore have adequate resources for the detection and control of outbreaks.

C4.5 Disease surveillance in office-based practice

All staff members in office-based practices need to be aware of the possibility that patients will present with suspected or confirmed infectious diseases.

For certain diseases, timely notification to the relevant authority will be required, sometimes by telephone. Systems need to be in place so that authorities are able to trace those with whom infectious patients have been in contact. A staff member should be responsible for checking national and state websites for relevant guidelines (RACGP 2006).

In most office-based practices, there will not be enough procedures performed to undertake outcome surveillance. Process surveillance can be used to evaluate processes and procedures and to monitor sentinel events. Systems should be in place for monitoring for threats of outbreaks (e.g. chickenpox [varicella], measles [rubeola]) and emerging diseases (e.g. H1N1, community-acquired MRSA [CA-MRSA]).

C4.6 Notifiable diseases

C4.6.1 Notifiable diseases

Notifiable diseases in Australia are listed at:

Certain diseases are listed as quarantinable under the Quarantine Act 1908 (Commonwealth) and its proclamations. These include yellow fever, cholera, plague, rabies and four viral haemorrhagic fevers (Crimean–Congo, Ebola, Lassa and Marburg). Quarantinable diseases are also notifiable and public health authorities in the relevant jurisdiction must notify their Chief Medical Officer.

C4.6.2 State and territory health departments

Public health legislation in each state and territory mandates the reporting of certain diseases by medical practitioners, hospitals, and/or laboratories to the relevant state or territory Communicable Diseases Unit. Notifications are collected at the state/territory level, and computerised, de-identified records are sent to the Australian Government Department of Health and Ageing for collation into the National Notifiable Diseases Surveillance System (NNDSS) for analysis at a national level. NNDSS was established in consultation with the Communicable Diseases Network Australia (CDNA).

Links to state and territory public health legislation can be found at:
C5 Antibiotic stewardship

Summary

• Inappropriate antibiotic use hastens the emergence and amplification of resistant pathogens and subsequent transmission among patients in healthcare facilities. This can have a significant impact on morbidity, mortality and treatment costs.
• Antibiotic stewardship programs aim to change antibiotic prescribing to decrease unnecessary use, reserve so-called last-line agents, and promote the use of agents less likely to select resistant bacteria. All activities are informed by guidelines and demonstrated incidence of antibiotic resistance.
• Surveillance data can be used to identify changes in usage that may be linked to development of resistance and to measure the impact of antibiotic stewardship programs.

C5.1 Background

There is a well-documented relationship between prior antibiotic usage and the emergence of bacterial resistance (McGowan 1987). WHO and other international bodies have nominated antibiotic resistance as a major public health concern, and the ACSQHC has established a national Antibiotic Stewardship Program to facilitate the establishment of effective antibiotic stewardship programs at national, state, healthcare facility and community levels.

The use of particular antibiotic classes is linked with the emergence and amplification of specific multi-resistant pathogens, particularly C. difficile, MRSA, VRE and multi-resistant Gram-negative organisms. If unchecked, high levels of antibiotic usage increase the number of patients who are colonised or infected with resistant organisms, both in healthcare facilities and in the community (Cosgrove & Carmeli 2003; van de Sande-Bruinsma et al 2008).

C5.1.1 In healthcare facilities

Comparison with international data shows that Australian antibiotic usage rates in healthcare facilities are high for some classes of drugs, and there is considerable unexplained variation between hospitals in the use of certain antibiotics, particularly broad-spectrum antibiotics (NAUSP 2007). Month-to-month variation in use of specific antibiotic classes has been shown to correlate closely with subsequent variation in antibiotic resistance (e.g. changes in hospital MRSA incidence) (Lopez-Lozano 2000).

Problems resulting from inappropriate use of antibiotics apply to both current and future healthcare facility patients due to changes in healthcare facility microbial ecology resulting from the resistance.

Additional costs of infections caused by resistant organisms include:
• the need for more expensive and broader spectrum antibiotics to treat the infections
• the need to isolate patients colonised with resistant organisms in order to minimise cross-infection.

C5.1.2 In the community

In the 1990s, community antibiotic use in Australia was high compared with other developed nations (McManus et al 1997). Today, multi-resistant bacteria, such as community strains of MRSA (CA-MRSA) and extended-spectrum beta-lactamase-producing Gram-negative bacteria, are causing increasing human morbidity and there is concern that past excessive antibiotic use in the community or in animal production systems (or both) is responsible.

National Prescribing Service (NPS) targeting of antibiotic prescribing contributed to a significant decline in antibiotic prescribing between 1999 and 2004 (NAUSP 2008), but this decline has not been sustained. There is currently no comprehensive system to monitor changes in resistance prevalence as a result of altered prescribing patterns. Most monitoring is done at the institutional level, except in Queensland, which has a system for monitoring resistance in its public hospitals.

C5.1.3 What is antibiotic stewardship?

Antibiotic stewardship aims to optimise antimicrobial use among patients in order to reduce antibiotic resistance, improve patient outcomes and safety, and ensure cost-effective therapy. At the healthcare facility level, antibiotic stewardship involves:

• implementing an antibiotic stewardship program; and
• continual monitoring and analysis of antibiotic usage, to track changes in antibiotic resistance and to monitor effects of containment strategies.

C5.2 Antibiotic stewardship programs

Intervention programs that restrict the use of broad-spectrum antibiotics have shown dramatic effects in optimising antibiotic prescribing. Successful antibiotic stewardship programs have been associated with reduced facility resistance rates as well as morbidity, mortality and associated costs of these and some Australian hospitals have also demonstrated significant cost savings through reduction in drug costs.

The density of antibiotic use within specialised units such as intensive care units, haematology and oncology units, and solid-organ transplant units is several-fold higher than in other hospital settings. This increased use has been shown to generate high rates of antibiotic resistance; therefore, these areas should be a particular focus for surveillance and intervention.

Key requirements of a healthcare facility antibiotic stewardship program are listed in Table C4.
Table C4: Key requirements of a healthcare facility antibiotic stewardship program

Case study—effect of an active antibiotic stewardship program

A large tertiary teaching hospital in New South Wales has had an active approach to antibiotic stewardship for many years. It is underpinned by locally relevant antibiotic guidelines and enthusiastic staff in the areas of pharmacy, infectious diseases and microbiology. Clinical teams are regularly engaged in guideline review, development and implementation at local and national levels. Specific discussions about patients are prompted by an online anti-infective registration (approval) system, where clinicians who prescribe broad-spectrum agents register the indication for use and are advised on correct dosage. Twice-weekly infectious diseases and microbiology patient rounds take place in ICUs. These frequently lead to changes in antibiotic therapy, generally to early cessation.

A drug usage evaluation pharmacist regularly audits antibiotic use for particular agents or clinical syndromes or situations, mainly community-acquired pneumonia and surgical prophylaxis. These audit data are used to provide feedback to clinicians to encourage more appropriate use.

Monthly data on usage are supplied to the National Antimicrobial Utilisation Surveillance Program. This allows for benchmarking of intensive care unit and non-intensive care usage against other large Australian hospitals. A study of usage of selected high-cost (predominantly broad-spectrum) antibiotics in 2006 indicated that, for most agents, use in intensive care unit and non-intensive care situations in this hospital was far lower than the national average. Based on purchase cost alone, the net cost difference in 2006 was $278,000 ($59,000 of this was for intensive care unit use).
C5.3 Antibiotic stewardship surveillance methods

C5.3.1 Healthcare facilities

There are two main methods of antibiotic data collection in healthcare facilities: patient level surveillance and population surveillance.

- **Patient level surveillance** involves collecting data about the dose, dosage interval and duration of therapy for individual patients. This approach gives the most accurate information, particularly if the aim is to link excessive antibiotic use with development of resistance in a particular area of practice. Such information is usually only available through reviews of drug usage, although electronic prescribing and recording of drug administration will make patient level surveillance more practical in the future.

- **Population-surveillance** involves aggregating antibiotic use data, mostly supplied through pharmacy reports, and summarised at the level of a hospital or unit. Currently, this type of surveillance is the only realistic alternative for ongoing and systematic monitoring of antibiotic use. In most hospitals in Australia, aggregate data from issues to wards combined with individual patient dispensing records are used. Another data collection method is to use pharmacy purchase data; however, this is less representative than aggregation of ward issues and individual inpatient supplies.

South Australia and Queensland have programs for state-wide monitoring of antibiotic usage. The National Antimicrobial Utilisation Surveillance Program provides bi-monthly reports on hospital inpatient antibiotic usage to contributing hospitals, and bi-monthly reports to the Australian Department of Health and Ageing. Data are contributed by 50% of principal referral hospitals from six states, which is currently 42% of major city principal referral centres.

C5.3.2 Community

Measurement of community antibiotic use is generally based on prescription data. In Australia, this is collected from two sources: Medicare Australia records of prescriptions submitted for payment under the Pharmaceutical Benefits Scheme (PBS) and Repatriation Pharmaceutical Benefits Scheme (RPBS); and an estimate of non-subsidised medicines obtained from an ongoing survey of a representative sample of community pharmacies. These data also include antibiotics dispensed to outpatients and discharged patients in most states.
C6 Influence of facility design on healthcare-associated infection

Summary

The design of a healthcare facility can influence the transmission of healthcare-associated infections by air, water and contact with the physical environment. Key design features that minimise the transmission of infection include:

- surface finishes that are easy to maintain and clean (floors, walls, benches, fixtures and fittings);
- ventilation, air conditioning, cooling towers and water systems that meet Australian standards for the facility they are to service;
- the ability to isolate patients:
  - in a single room (infectious patients) or negative pressure room (to prevent transmission of airborne pathogens)
  - positive pressure rooms or use of laminar airflow filtration (LAF) for immunocompromised patients
- triaging of patients in waiting rooms with separation of infectious patients;
- appropriate work place design:
  - separation of procedural and cleaning areas
  - movement of work flow systems
  - ready access to hand hygiene facilities
  - adequate storage for all patient-care items;
  - easily accessible storage for PPE;
  - adequate waste management procedures and linen handling; and
- involvement in demolition, construction and renovation projects of a multidisciplinary team that includes infection prevention and control staff to coordinate preventive measures.

C6.1 Facility design and its impact on infection prevention and control

Infection prevention and control requirements are critical to the planning of a healthcare facility and need to be incorporated into plans and specifications. All areas of a healthcare facility should be designed, constructed, furnished and equipped to minimise the risk of transmission of infection. In particular, the design and layout of the facility should facilitate the application of standard and transmission-based precautions by all staff.

C6.1.1 Evidence on the influence of environmental design on healthcare-associated infection

There are few randomised controlled trials relevant to the effects of specific design features or interventions on health outcomes. However, from case reports, published literature relating to outbreaks and from a theoretical risk-management perspective, it is clear that the design of buildings can have an impact on rates of HAIs. Reliable patterns across several studies emerged, which were broadly consistent with predictions based on established knowledge and theory concerning environment and healthcare outcomes.

However, it is difficult to distinguish the independent effect of any environmental factor, as most changes of the physical environment in healthcare settings alter several environmental factors simultaneously. For example, renovating an intensive care unit with two-bed patient rooms to create single-bed rooms would be likely to alter not only the number of patients per room, but also the ratio of hand-hygiene sinks per bed and possibly the room ventilation or air quality.
C6.2 Mechanisms for influencing healthcare-associated infection through environmental design

Many studies indicate that infection rates are lower when there is very good air and water quality, greater physical separation of patients and greater space per patient (with isolation where appropriate).

C6.2.1 Reducing airborne transmission

Reservoirs for airborne pathogens include (Ulrich & Wilson 2006):

- dust (e.g. spores of *C. difficile* or *Aspergillus*)
- aerosols (e.g. TB, severe acute respiratory syndrome [SARS], influenza, chickenpox)
- skin scales shed by patients infected with MRSA.

Airborne transmission has also been implicated in outbreaks of other infections such as *Acinetobacter* and *Pseudomonas* spp. (Beggs 2003; Beggs et al 2008).

Most pathogens in healthcare settings originate from patients, staff and visitors within the buildings. Other pathogens can enter buildings from outside air through dust that harbours pathogens such as *Aspergillus*, streptococci or staphylococci (Beggs 2003). There are also less common sources of airborne infections; for example, bird droppings or aerosols from contaminated water in a warm-water therapy pool (Angenent et al 2005).

Approaches to airborne transmission

Approaches to reducing airborne transmission include:

- installation of effective air filtration
- specifying appropriate ventilation systems and air change rates (e.g. negative airflow pressure)
- employing monitoring and control measures during construction or renovation
- using single-bed instead of multi-bed rooms.

In dental practices, engineering rules state there must be separation between inlet air for compressors and air conditioning outlets (ADA 2008).

Filtration

An effective way to prevent infections is to control the source of pathogens. Heating, ventilation and air-conditioning systems control the concentration of airborne particulates in high risk areas, to minimise the risk of infection by means of air pressure, flow control and air filtration (the physical removal of particulates from air). The level of control should be proportional to the risk.

In acute healthcare settings, a commonly used approach to filtration is the HEPA filter (Streifel 1999). There is evidence that there is a lower incidence of infection when immunocompromised and other high-acuity patients are housed in HEPA-filtered isolation rooms. HEPA filters must comply with AS 1324 and AS 4260.
Ventilation systems and airflow control

Optimal ventilation rates, airflow patterns and humidity can help to minimise the spread of infection.

- The ventilation rate is a measure used to control indoor air quality, and in healthcare facilities is usually expressed as room air changes per hour (ACH). The peak efficiency for particle removal in the air space often occurs between 12 ACH and 15 ACH—Australian guidelines recommend that isolation rooms have a minimum of 12 ACH or 145L/sec whichever is greater (NSW Health 2007), and other rooms in Australian healthcare facilities are required to comply with AS1688.2 (1991). However, there is a lack of consistency in the minimum ventilation requirements needed for effective prevention of infections. A study of 17 Canadian hospitals found that the risk of healthcare workers acquiring TB was strongly linked with exposure to infected patients in rooms with low ACH rates, such as waiting areas (Menzies et al 2000).

- Airflow direction is also important:
  - **Negative airflow pressure** is preferred for rooms housing infectious patients to prevent the dispersion of pathogen-laden aerosols (e.g. measles [rubeola], TB, chickenpox [varicella]), dust and skin scales from the locus of the infected patient to other spaces. A review of 40 studies concluded that there is strong evidence to support and recommend the use of negatively pressurised isolation rooms (Li et al 2007).
  - **Positive airflow pressure** is desirable to safeguard them from aerial pathogens entering from adjacent spaces in the care of immunocompromised patients (e.g. surgical patients, patients with underlying chronic lung disease, or dialysis patients) or immunosuppressed patients (e.g. transplant patients or cancer patients).
  - **Laminar air flow (LAF)** is HEPA-filtered air blown into a room at a rate of $27 \pm 3$ m/min in a unidirectional pattern with 100–400 ACH (Sehulster et al 2004). LAF can reduce air contamination to the lowest possible level and is therefore recommended for operating rooms and areas with ultraclean room requirements (e.g. immunocompromised patients) (Alberti et al 2001; Arlet et al 1989; Dharan & Pittet 2002; Friberg et al 2003; Hahn et al 2002; Sherertz et al 1987).

Maintenance systems

Ventilation and airflow control systems need to be maintained regularly by suitably qualified staff according to an agreed maintenance plan, and accurate documented in a maintenance record.

Maintaining air quality during construction or renovation

Effective control and prevention measures are necessary during construction and renovation within a healthcare facility, because such activities have been frequently implicated in outbreaks of airborne infection. The key to eliminating infections is to minimise the dust generated during the construction activity and to prevent dust infiltration into patient-care areas near the construction. Examples of such measures include installing barriers between patient-care areas and construction/renovation areas, generating negative air pressure for construction/renovation areas relative to patient-care areas, using portable HEPA filters and sealing patient windows.

C6.2.2 Reducing infections spread through the physical environment

The prevention of contact-spread infections is of paramount importance in healthcare settings. Contact contamination is generally recognised as the principal transmission route of healthcare acquired infections, including pathogens such as MRSA, C. difficile and VRE, which survive well on environmental surfaces and other reservoirs.

Environmental routes of contact-spread infections include direct person-to-person contact and indirect transmission via environmental surfaces.

Reducing surface contamination through hand-hygiene compliance

Healthcare workers’ hands play a key role in both direct and indirect transmission (see Sections B1.1 and C3.4). Given the importance of maximising hand-hygiene compliance, it is absolutely essential that all areas of the facility are designed to facilitate compliance with hand-hygiene requirements.

Accessibility

Conveniently located alcohol-based product dispensers, sinks and basins can facilitate healthcare worker compliance with hand-hygiene requirements (Grayson et al 2009).

Hand-hygiene compliance can be increased by providing a greater number of alcohol-based product dispensers, particularly if they are placed in appropriate locations (where clinical care is provided [e.g. bedside] or where indirect care tasks are performed). Other aspects of design that may increase compliance include automated dispensers of hand-hygiene products, electronic monitoring and computerised voice prompts.

Consideration needs to be given to ensuring availability of basins for healthcare workers that are separate from patient bathrooms.

As well as being installed in all patient-care areas, hand-hygiene facilities should be placed in all areas where careful attention to hygiene is essential, such as kitchens, laundries, pharmacies, laboratories and staff amenities areas (e.g. bathrooms, toilets and change rooms).

Personal protective equipment

It is also essential that all areas of the facility are designed to facilitate appropriate use of PPE. All rooms should have dedicated and accessible areas for storage of gowns, aprons, gloves, masks and protective eyewear.

C6.2.3 Control of surface contamination through material selection

Ease of cleaning should be a key consideration in selecting appropriate floor and furniture coverings. Several design-related factors should be considered to minimise the risk of infection stemming from contaminated surfaces:

• the nature and type of contamination that is likely to occur
• if a suitable cleaning method for that surface can be performed.

Areas that may be in direct contact with blood and body substances (e.g. surfaces such as floors and bench tops) need to be made of impervious material that is smooth and easy to clean.
Healthcare flooring

A wide range of floor covering materials is used in healthcare settings. These include but are not limited to: ceramic tiling, linoleum, rubber, textile floor covering, vinyl, sheet terrazzo, cork, timber laminates, mats and matting, cementinous toppings, seamless coatings and outdoor flooring.

Floor coverings have not been generally related to healthcare associated infection. Some studies have identified carpeting as susceptible to contamination by fungi and bacteria (Anderson et al 1982; Boyce et al 1997; Skoutelis et al 1994; Beyer & Belsito 2000).

When selecting floor covering for a health care setting consideration needs to be given to the following:

• Who is at risk of acquiring infection?
• What is the risk of exposure to the infectious agents?
• What is the nature of the possible infectious agents?
• How can the agent be transmitted? (eg airborne; through cleaning techniques; through contact especially in environments in which there are young children)

In terms of infection prevention and control, the advantages of hard floor coverings include:

• being easier to clean
• being easier to disinfect where required
• allowing use of the most appropriate disinfectant, rather than a product that is suitable for use on carpet
• costing less, as disinfectant is less expensive than steam cleaning, and steam cleaning may not be readily available
• there is less surface area so hard floor coverings are less likely to act as a reservoir of infectious agents than carpet
• when additional cleaning is required, hard floor surfaces are easier to clean than carpet.

However, carpeting may offer advantages unrelated to infection prevention and control, including noise reduction (Philbin & Gray 2002). Textile floor finishes should not be considered unless there is a comprehensive maintenance and replacement program in place complying with AS/NZS 3733. Care and maintenance of floor covering need to consider manufacturer’s recommendations.

Carpeting should be avoided in areas where (Sehulster & Chinn 2003):

• spills are likely to occur (e.g. around sinks or in isolation or soiled utility/holding areas)
• patients may have direct contact with contaminated carpets (e.g. children/babies crawling on the floor)
• patients are at greater risk of airborne infections.

Furnishings

A study comparing the performance of a variety of furniture upholstery types with respect to VRE and Pseudomonas aeruginosa (PSAE) contamination (Lankford et al 2006) found that performance was similar across different furniture coverings in terms of reductions in VRE and PSAE after cleaning and the transfer of VRE and PSAE to hands through contact. However, while there were no differences in the ability of different upholstery types to harbour PSAE, the VRE pathogen survived less well or for shorter periods on vinyl (Lankford et al 2006).
The CDC/HICPAC guidelines (Sehulster & Chinn 2003) recommend minimising the use of upholstered furniture in areas housing immunocompromised patients.

Blinds and curtains should be easy to clean and discourage the accumulation of dust.

C.6.2.4 Reducing water-borne transmission

Compared with airborne and contact transmission of infection, fewer studies were identified on waterborne transmission in relation to healthcare facility design factors. The literature nonetheless is clear that waterborne infections can be a serious threat to patient safety. Many bacterial and some protozoal microorganisms can proliferate or remain viable in moist environments or aqueous solutions in healthcare settings (Sehulster et al 2004).

Contaminated water systems in healthcare settings (such as inadequately treated wastewater) may lead to the pollution of municipal water systems, enter surface or ground water, and affect people in the community (Iversen et al 2004).

Sources of water contamination

The CDC/HICPAC guidelines (Sehulster & Chinn 2003) identify the following categories of environmental routes or sources of waterborne transmission:

- direct contact, such as hydrotherapy (Angenent et al 2005)
- ingestion of water, such as drinking water (Conger et al 2004; Squier et al 2000)
- inhalation of aerosols dispersed from contaminated water sources, such as improperly cleaned or maintained cooling towers, showers (Mineshita et al 2005), respiratory therapy equipment and room air humidifiers
- aspiration of contaminated water.

Approaches to reducing waterborne transmission

Water supply system

The water supply system should be designed and maintained with proper temperature and adequate pressure; stagnation and back flow should be minimised and dead-end pipes should be avoided.

To prevent the growth of Legionella and other bacteria, the CDC/HICPAC guidelines recommend that healthcare facilities maintain cold water at a temperature below 20°C, store hot water above 60°C, and circulate hot water with a minimum return temperature of 51°C (Sehulster & Chinn 2003).

When the recommended standards cannot be achieved because of inadequate facilities that are unable to be renovated, other measures such as chlorine treatment, copper-silver ionisation, or ultraviolet lights are recommended to ensure water quality and prevent infection (Sehulster & Chinn 2003).

Point-of-use fixtures

Water fixtures such as sinks, faucets, aerators, showers, and toilets have been identified as potential reservoirs for pathogenic microorganisms (Blanc et al 2004; Conger et al 2004; Mineshita et al 2005; Squier et al 2000). Such fixtures produce aerosols that can disperse microbes and they have wet surfaces on which moulds and other microorganisms can proliferate. However, empirical evidence linking these fixtures to HAIs is still limited; no consensus has been reached regarding the disinfection or removal of these devices for general use (Sehulster et al 2004).
Regular cleaning, disinfection and preventative maintenance programs should be provided, especially in areas housing immunocompromised patients.

**Ice machines**

Ice storage receptacles and ice-making machines should be properly maintained and regularly cleaned. Ice and ice-making machines may be contaminated through improper handling of ice by patients and/or staff. Ice for human consumption should be differentiated from ice for first aid or storage of clinical specimens. Pharmaceuticals or medical solutions should not be stored on ice intended for consumption.

Machines that dispense ice are preferable to those that require ice to be removed from bins or chests with a scoop. Ice machines and their dispensers should be flushed and cleaned if they have not been disconnected before anticipated lengthy water disruptions.

All ice-storage chests should be cleaned, disinfected, and maintained on a regular basis as per manufacturers instructions.

Suggested steps to avoid improper handling of ice include (Sehulster & Chinn 2003):

• avoiding handling ice directly by hand
• washing hands before obtaining ice
• using a smooth-surface ice scoop to dispense ice
• keeping the ice scoop on a chain short enough that the scoop cannot touch the floor, or keeping the scoop on a clean, hard surface when not in use
• avoiding storing the ice scoop in the ice bin.

**Water features**

Despite the absence of empirical documentation linking properly maintained fountains to healthcare-acquired infections, the AIA & FGI Guidelines (2006) recommend that fountains not be installed in enclosed spaces in healthcare facilities.

**C6.3 The benefits of single-bed rooms for patient isolation**

The three routes of transmission often overlap, and environmental approaches may influence more than one transmission route. For example, single rooms play a key role in preventing a patient with a contagious or aerial spread infection from infecting others, and also protect immunocompromised patients in nearby patient-care areas from airborne pathogens.

• Studies of cross-infection for contagious airborne diseases (such as TB, measles [rubeola], and chickenpox [varicella]) indicate that placing patients in single rooms, single-bed cubicles with partitions, isolation rooms, or rooms with fewer beds and more space between patients, is safer than housing them in multi-bed spaces with more patients.
• Surfaces near infected patients quickly become contaminated, creating numerous reservoirs that can transfer pathogens to patients and staff.
• Screening for MROs or specific pathogens is effective but results may not be available on admission; placing MRO colonised/infected patients with non-colonised /infected patients in multi-bed rooms increases the spread of MROs.
• Single-bed rooms can facilitate greater frequency of cleaning and decontamination, as there is limited impact on neighbouring patients.
• Hand-hygiene compliance is likely to be improved through greater prominence of sinks or hand hygiene dispensers.
• Ensuite bathrooms are a key factor in preventing the spread of *C. difficile* and other infectious agents that spread via enteric and contact mechanisms.
International bodies including the American Institute of Architects recommend that acute-care facilities have 80% single-bed rooms. This recommendation is being implemented in a number of current hospital redevelopments (e.g. Royal Canberra Hospital, Royal Perth Hospital) and should be considered during planning for redevelopment of any acute healthcare facility.

**Anterooms**

Anterooms enable visitors and healthcare workers to change into and dispose of appropriate PPE when caring for an infectious patient. Anterooms increase the effectiveness of isolation rooms by reducing the potential escape of airborne infectious particles into the corridor.

Ideally the pressure in the anteroom is lower than that of ambient pressure in the adjacent corridor (AusHFG).

### C6.4 Construction and renovation

Infection prevention and control precautions during construction and renovation should be integrated into the design and documentation of the facility from the beginning of the design stage. It is important that the dust control and infection prevention and control principles developed during the pre-design stage are integrated from the initial stages of design development until the completion of the activity.

Identification of the ‘at risk’ population, knowledge of the transmission route of a likely pathogen and location of the ‘at risk’ population all need to be taken into account in the planning stages.

#### C6.4.1 Risk management

The risk-management approach should, as a minimum:

- identify the location of high-risk patients in relation to the site
- identify ventilation system types and potential impact
- determine air monitoring requirements, methodology and frequency
- include taking of air quality samples to establish a baseline
- identify possible contaminants and their locations (contaminants may be present in ceiling dust, service shafts (especially if dampness is present), spray-on fire retardants and bird droppings.

Refer to Section D of the Australasian Health Facility Guidelines (AusHFG) for further guidance and the definition of infection prevention and control risk, location/area table and infection prevention and control strategies.
C7 Resources

C7.1 Management and clinical governance

- ACSQHC Resources
  - Measurement for improvement tool kit

- CDC Workbook for Designing, Implementing, and Evaluating a Sharps Injury Prevention Program

C7.2 Staff health and safety

Occupational health and safety

Pre-employment screening and Immunisation

Legislation/ policy

Each state and territory has numerous legislation/ Acts relating to occupational health and safety, workers compensation and the employers responsibility to provide a safe work environment.

Immunisation of health care workers is an aspect of occupational health and safety in the health care setting. Each state has its own policies, examples are provided below:

- Health Department Policy Directive 2007_006 Occupational Assessment, Screening & Vaccination Against Specified Infectious Diseases

Guidelines

- National Immunisation Program Schedule – 2007 DoHA

Exposure to blood and blood products

Legislation/codes of practice

Each state has its own policies, examples are provided below:

**NSW**

**WA**

**QLD**

Post-exposure prophylaxis

Terms of Reference

The Infection Control Steering Committee (the Committee) will oversee and provide expertise in the revision of the *Infection control guidelines for the prevention of transmission of infectious disease in the health care setting* (2004) (the Guidelines).

1. The revision will take into account but not be limited to:
   - The best available current scientific evidence.
   - NHMRC recommended standards on guideline development.
   - Comments provided by the broader community and health care sector through feedback from the project’s stakeholder group, targeted consultations and public consultation.

2. The Committee will provide advice on the following areas of the Guidelines revision:
   - The scope and requirements of the systematic review
   - The formulation of recommendations from the results of the systematic review
   - The content of the Guidelines
   - The development of educational materials and companion documents
   - Identification of indicators for the purpose of evaluation and monitoring the guidelines implementation
   - The development of an implementation strategy
   - Key stakeholders to undertake liaison/consultation.

3. The Committee will provide regular reports on the progress of guideline development to the CEO of the NHMRC.

4. The Committee will provide the NHMRC CEO with a draft report for the CEO to seek advice from Council.
APPENDIX 2

PROCESS REPORT

The NHMRC was approached by the Australian Commission on Safety and Quality in Health Care (the Commission) in November 2007 to review and update the *Infection control guidelines for the prevention of transmission of infectious diseases in the health care setting*. These guidelines were produced by the Communicable Diseases Network Australia (CDNA) and released in 2004.

The NHMRC revised guideline (the Guideline) aimed to provide a coordinated approach to the management of health care associated infection (HAI) in Australia by supporting the Commission's other HAI priority program initiatives including the:

- National HAI Surveillance Strategy
- Hand Hygiene Initiative
- Antibiotic Stewardship.

The NHMRC developed a range of partnerships to support and assist in the guideline development process including the NHMRC's National Institute of Clinical Studies, CDNA, the Office of Health Protection in the Australian Government Department of Health and Ageing, the Commission and guideline users.

The project plan for the revision of the guidelines was approved by the NHMRC Acting Chief Knowledge Development Officer on 25 January 2008. The Infection Control Guidelines Steering Committee (the Committee) was established under the *NHMRC Act* (1992) as a Section 39 committee, and was chaired by Dr Ann Koehler, the South Australian representative of the CDNA. The committee was first established with eight members, comprising of experts in microbiology and infectious disease, public health, Indigenous health as well as jurisdictional representatives and infection control professionals. During 2008, two Committee members resigned from the Committee (Ms Dolly Oleson and Ms Claire Boardman) but an additional five members were appointed to broaden the expertise of the Committee. The Committee from November 2008 until the completion of the project is outlined in Appendix 1.

Appointment of technical writers

Ampersand Health Science Writing was selected through a Request for Quote process from the NHMRC Technical Writers and Editors Panel. The two key personnel from Ampersand working on this project were Ms Elizabeth Hall and Ms Jenny Ramson, who participated in the forums and Steering Committee meetings to gain an understanding of the issues and the context of the infection control guidelines.
Scope

The Guideline targets clinicians, ancillary staff and administrators across Australia’s various health care settings. Initial feedback indicated that the following health care settings should be considered when developing the guidelines:

- private and public acute care
- long-term care
- community health including home care
- remote area health services
- office based practices involved in invasive procedures such as dental, obstetrics and gynaecology, ophthalmology, surgical and general practice.

As a means of addressing this broad scope of practice it was decided that the guidelines would be structured to address the ‘core principles’ of infection prevention and control and the underpinning key practice principles. The core principle of infection prevention and control is to prevent the transmission of infectious organisms and manage infections if they occur. The underpinning key practice principles include:

1. an understanding of the modes of transmission of infectious agents and an overview of risk management
2. effective work practices that minimise the risk of selection and transmission of infectious agents
3. governance structures that support the implementation, monitoring and reporting of infection prevention and control work practices
4. compliance with legislation, regulations and standards relevant to infection prevention and control.

It is acknowledged there may be variation in some current practices due to differences in technology, resources and systems supporting a healthcare facility. To address this, a risk-management approach was adopted that considers how factors associated with the transmission of infectious agents can be identified and managed within various health care settings. This approach ensures that common infections such as gastrointestinal viruses and evolving infectious agents such as influenza or antibiotic resistant bacteria can be managed effectively using the principles of infection prevention and control.

Preliminary scoping

The initial focus of the project was to liaise with stakeholders across a broad range of healthcare settings to identify the usefulness and applicability of the 2004 guidelines. This was managed through stakeholder surveys and a series of organised forums. The stakeholder survey was developed to allow participants and the organisations they represented to consider the issues prior to attending the forums. The survey was targeted towards state-based infection control professional associations, public health medical officers and the aged care accreditation alliance. This survey was circulated to stakeholders participating in forums to gather feedback on the guidelines and to organisations wishing to provide feedback but unable to attend the forums.

Stakeholder forums

Stakeholder forums were conducted in Sydney, Canberra and Melbourne in early March 2008, and were facilitated by Carla Granny & Associates. In all, 59 representatives from various health care settings, the medical device industry, professional associations, health care funders and government agencies attended. The purpose of the forums was to gain feedback from stakeholders in the healthcare setting on the usefulness and applicability of the 2004 guidelines as well as identify gaps and areas of ambiguity in the guidelines.
The forums identified:

• current gaps in the 2004 guidelines, in particular the need for better guidance on:

  – healthcare worker infection prevention and control issues
  – pandemic planning
  – sterilisation and reprocessing of equipment
  – environmental cleaning and waste management
  – MROs - management of patients in the various health care settings
  – the impact of healthcare facility design on infection prevention and control
  – the scope of practice of infection control professionals and guidance on staffing profiles across the range of service settings

• areas of uncertainty or clinical variation in infection prevention and control practice

• barriers to implementation of the guidelines including cross references to guidance that is not freely available; healthcare worker attitudes and behaviours and the lack of accountability of health care managers

• additional tools required to support implementation

• options on formatting and presentation.

Priority setting

The stakeholder forums identified several key areas the guidelines need to address. These issues relate to: emerging pathogens; screening and clearance of patients with MRO infections; areas where gaps in evidence resulted in variation in clinical practice; and medical device technology.

Using the feedback from the forums, the Committee actively engaged with stakeholders across the healthcare setting to seek feedback on the priority areas the revised infection prevention and control guidelines should address. With significant input from the Australian Infection Control Association, the Committee carefully considered and systematically identified the priority areas of infection prevention and control that need to be addressed by the guidelines. The Committee developed a framework encompassing the broad scope of infection prevention and control activities across the health care setting. Priority areas identified at the forums and by the Committee were placed in the framework and then ranked according to which issues have the greatest impact on infection prevention and control.

From this priority-setting exercise, the Committee identified the key issues that required further research. These issues formed the basis for the development of the clinical questions for systematic review.

Systematic review of the evidence

The recommendations for the Guideline were developed using a twofold approach.

• For areas where clinical variation exists or it is considered there are emerging issues in infection prevention and control, systematic reviews of the literature were conducted to gather the evidence for the specific guideline section. The NHMRC level and grades pilot program was implemented in reviewing and synthesising the evidence.

• For areas of established practice, recommendations from current national and international guidelines were adapted for an Australian context by the Committee. Guidelines were selected according to their currency and clinical relevance and were appraised using the Appraisal of Guidelines for Research and Evaluation (AGREE) instrument to assess the rigor with which they had been developed.
Drafting of clinical questions for systematic review

Dr Adele Weston, a member of the NHMRC evidence-based medicine expert panel, attended the 12 May committee meeting to inform the members on the NHMRC systematic review process including how recommendations are drafted from the evidence. The clinical questions commenced being drafted at that meeting using the population, intervention, comparator, outcome, time (PICOT) approach. They were further refined, circulated and discussed via a series of teleconferences before being released in a Request for Tender in July 2008. The questions are outlined below.

Table App2.1: Clinical questions for systematic review

<table>
<thead>
<tr>
<th>QUESTION</th>

</table>

The Request for Tender process was ultimately unsuccessful and systematic reviewers were approached using a Request for Quote or Direct Sourcing approach. The systematic reviews were conducted by the following:
A number of clinical questions that were identified as a priority were unable to be conducted due to resource constraints. These included:

1. Does the use of retractable devices show a decreased rate in the incidence of sharps injuries for healthcare workers?
2. Is there a decreased incidence of stick injuries for healthcare workers using automated cleaning practices compared to manual cleaning practices?
3. Can the risk factors for nosocomial infections in healthcare facilities be identified and ranked according to relative risk? Risk factors could include bed occupancy levels, staffing ratios and building design.

Due to a paucity of evidence or low quality evidence some systematic reviews were not used to draft recommendations. These include:

- effectiveness of environmental cleaning agents
- decolonisation of MROs
- patient screening for MROs
- efficacy of negative pressure rooms.

Recommendations for these areas were drawn from existing guidelines and supported by expert opinion. The education review to identify strategies to improve hand-hygiene compliance was incorporated into Section C Governance structures, which contains no graded recommendations for practice.

The systematic reviews for:

- intravascular device management
- hand-hygiene products
- effectiveness of isolation for VRE and MRGN
- effectiveness of PPE in reducing VRE and MRSA transmission
- staff exclusion periods for norovirus
- efficacy of positive pressure rooms

were conducted according to approved NHMRC processes and systematic review methodology with a documented search strategy, inclusion and exclusion criteria, critical appraisal methodology and summary of the evidence. These systematic reviews are provided in the full report, which is available on the NHMRC website. The systematic reviewer summarised the questions and sub questions into the NHMRC template, which documents the evidence base (number of studies, level of evidence and risk of bias in the included studies), consistency, clinical impact, generalisability and applicability.
The NHMRC template was used by the Steering Committee to draft evidence statements and recommendations corresponding to the summary of evidence provided by the systematic reviewer. These evidence statements and recommendations are summarised in Attachment 2b of the full report. The grades assigned by the systematic reviewers are documented with the corresponding grades assigned by the Committee. The grades were assigned by the Committee via teleconferences and meetings with the final recommendations and grading outlined in Attachment 2c of the full report. Dissenting opinions were noted.

Development of recommendations from guidelines and standards

As a part of the prioritisation process a mapping exercise was conducted to identify relevant guidelines and standards that existed nationally and internationally on infection prevention and control in the health care setting. Links to standards and legislation relevant to infection prevention and control that were identified will be included at the end of each relevant section. It is envisaged that targeted and public consultation will provide more feedback in this section.

For areas of established practice not covered by the systematic review, guidelines developed using rigorous methodology were used to adapt recommendations from for an Australian context. Guidelines were identified by a combination of literature searches, current use in practice and by the ICG Committee. Guidelines were selected according to their currency and clinical relevance and were appraised using the Appraisal of Guidelines for Research and Evaluation (AGREE) instrument to assess the rigor with which they had been developed. The AGREE scores were calculated across the six domains and used to identify which guidelines to use. The NHMRC engaged numerous stakeholders identified during the forums and through the Commission to assist with the appraisal of the guidelines.

Three reviewers per guideline with appropriate clinical experience in infection prevention and control, infectious diseases or guideline development reviewed each guideline. The reviewers included Committee members, the Commissions’ Health Care associated Infection Implementation Advisory Committee and members of the Australian Dental Association.

Reviewers were asked to rate an item on a scale of 1 to 4, with 1 being ‘strongly disagree’ and 4 being ‘strongly agree’. Domain scores were calculated by summing up all the scores of the individual items in a domain and by standardising the total as a percentage of the maximum possible score for that domain. Generally, a higher score indicates the guideline rated well against the AGREE criteria.

The six domains were:

• scope and purpose
• stakeholder involvement
• rigour of development
• clarity and presentation
• applicability
• editorial independence.
An overall assessment and recommendation was provided by each reviewer. Guidelines selected to draft recommendations from were:

- United States Centre for Disease Control and Prevention (CDC)
  - Guidelines for infection control in the dental setting (2003)
  - Guidelines for environmental infection control in health-care facilities (2003)
  - Workbook for Designing, Implementing, and Evaluating a Sharps Injury Prevention Program (2008)

- WHO Guidelines on Hand Hygiene in Health Care (2009)

- National Institute of Clinical Excellence—Surgical site infection prevention and treatment of surgical site infection (2008)

- US government website pandemicflu.gov (2006)—Interim Guidance on Planning for the Use of Surgical Masks and Respirators in Health Care Settings during an Influenza Pandemic

Relevant recommendations were drawn out of each approved guideline and categorised appropriately by the technical writers. These recommendations were circulated to committee members and additional infection prevention and control representatives in topic subgroups, to prioritise what should be used in the guidelines. Comments were collated by the NHMRC and the technical writers and the recommendations chosen for the guideline were refined at a face-to-face meeting. The approach taken to consensus setting was developed in consultation with NICS and comprised attributes of the Delphi and RAND/UCLA processes.

These recommendations were prioritised and then regraded from their original guideline grading to an NHMRC grading based on matching criteria from the original guideline developers. The Committee considered these grades and dissenting comments were noted. The recommendations with their original grading and the assigned NHMRC grading are summarised in Attachment 2c of the full report.

A preliminary draft was provided to jurisdictions for feedback in October 2009. A summary of the feedback and NHMRC responses is provided in Attachment 2d of the full report.
Glossary

This section outlines the way in which certain terms are used in these guidelines.

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acinetobacter</td>
<td>An aerobic Gram-negative bacillus commonly isolated from the hospital environment (especially intensive care units) and hospitalised patients; can cause healthcare-associated infections, especially wound infections and pneumonia.</td>
</tr>
<tr>
<td>Aerosols</td>
<td>Microscopic particles &lt; 5 µm in size that are the residue of evaporated droplets and are produced when a person coughs, sneezes, shouts, or sings. These particles can remain suspended in the air for prolonged periods of time and can be carried on normal air currents in a room or beyond, to adjacent spaces or areas receiving exhaust air.</td>
</tr>
<tr>
<td>Airborne precautions</td>
<td>A set of practices used for patients known or suspected to be infected with agents transmitted person-to-person by the airborne route.</td>
</tr>
<tr>
<td>Alcohol-based hand rub</td>
<td>A TGA-registered alcohol-containing preparation designed for reducing the number of viable microorganisms on the hands without the use or aid of running water and which is included on the ARTG as a medicinal product.</td>
</tr>
<tr>
<td>Anteroom</td>
<td>A small room leading from a corridor into a room.</td>
</tr>
<tr>
<td>Antibiogram</td>
<td>The result of a laboratory testing for the sensitivity of an isolated bacterial strain to different antibiotics.</td>
</tr>
<tr>
<td>Antibiotic</td>
<td>A substance that kills or inhibits the growth of bacteria, fungi or parasites.</td>
</tr>
<tr>
<td>Antisepsis</td>
<td>The use of chemical or physical methods to prevent infection by destroying or inhibiting the growth of harmful microorganisms.</td>
</tr>
<tr>
<td>Asepsis</td>
<td>‘Freedom from infection or infectious (pathogenic) material’.</td>
</tr>
<tr>
<td>Aseptic Non Touch Technique (ANTT)</td>
<td>A practice framework for aseptic technique.</td>
</tr>
<tr>
<td>Aseptic technique</td>
<td>An aseptic technique aims to prevent microorganisms on hands, surfaces and equipment from being introduced to susceptible sites. Therefore, unlike sterile techniques, aseptic techniques can be achieved in typical ward and home settings.</td>
</tr>
<tr>
<td>Bloodstream infection</td>
<td>The presence of live pathogens in the blood, causing an infection.</td>
</tr>
<tr>
<td>Bundle</td>
<td>A set of evidence-based practices that have been shown to improve outcomes when performed collectively and consistently. The concept was developed by the Institute for Healthcare Improvement in the United States to improve the care process and patient outcomes.</td>
</tr>
<tr>
<td>Catheter</td>
<td>A thin, flexible, hollow tube used to add or remove fluids from the body.</td>
</tr>
<tr>
<td>Clean technique</td>
<td>Clean technique refers to practices that reduce the number of infectious agents, and should be considered the minimum level of infection control for non-invasive patient-care activities. Practices include: personal hygiene, particularly hand hygiene, to reduce the number of infectious agents on the skin; use of barriers to reduce transmission of infectious agents (including proper handling and disposal of sharps); environmental cleaning; and reprocessing of equipment between patient uses.</td>
</tr>
<tr>
<td>Clinical waste</td>
<td>Waste material that consists wholly or partly of human or animal tissue, blood or body substances, excretions, drugs or other pharmaceutical products, swabs/dressings, syringes, needles or other sharp instruments.</td>
</tr>
<tr>
<td>Cohorting</td>
<td>Placing together in the same room patients who are infected with the same pathogen and are suitable roommates.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Colonisation</td>
<td>The sustained presence of replicating infectious agents on or in the body without the production of an immune response or disease.</td>
</tr>
<tr>
<td>Contact</td>
<td>The touching of any patient or their immediate surroundings or performing any procedure.</td>
</tr>
<tr>
<td>Contact point</td>
<td>The area of direct contact of skin to equipment.</td>
</tr>
<tr>
<td>Contact precautions</td>
<td>A set of practices used to prevent transmission of infectious agents that are spread by direct or indirect contact with the patient or the patient’s environment.</td>
</tr>
<tr>
<td>Decontamination</td>
<td>Use of physical or chemical means to remove, inactivate, or destroy pathogens on a surface or item so that they are no longer capable of transmitting infectious particles and the surface or item is rendered safe for handling, use, or disposal.</td>
</tr>
<tr>
<td>Detergent solution</td>
<td>A detergent product which is intended to be used in the cleaning of surfaces or other medical devices diluted with water as per manufacturer’s instructions.</td>
</tr>
<tr>
<td>Disinfectant</td>
<td>A TGA-registered disinfectant chemical product that is intended for use in disinfection of surfaces or medical devices.</td>
</tr>
<tr>
<td>Disinfection</td>
<td>Destruction of pathogenic and other kinds of microorganisms by physical or chemical means.</td>
</tr>
<tr>
<td>Droplet precautions</td>
<td>A set of practices used for patients known or suspected to be infected with agents transmitted by respiratory droplets.</td>
</tr>
<tr>
<td>Droplets</td>
<td>Small particles of moisture generated when a person coughs or sneezes, or when water is converted to a fine mist by an aerator or shower head. These particles, intermediate in size between drops and droplet nuclei, can contain infectious microorganisms and tend to quickly settle from the air such that risk of disease transmission is usually limited to persons in close proximity (e.g. at least 1 metre) to the droplet source.</td>
</tr>
<tr>
<td>Engineering controls</td>
<td>Removal or isolation of a workplace hazard through technology.</td>
</tr>
<tr>
<td>Epidemic</td>
<td>A widespread outbreak of an infectious disease. Many people are infected at the same time.</td>
</tr>
<tr>
<td>Fit check</td>
<td>A quick check to ensure that the respirator is fitting each time it is put on.</td>
</tr>
<tr>
<td>Fit test</td>
<td>A method of ensuring that a respirator is fitted correctly and suitable for use by a specific individual.</td>
</tr>
<tr>
<td>Hand hygiene</td>
<td>A general term applying to processes aiming to reduce the number of microorganisms on hands. This includes: application of a waterless antimicrobial agent (e.g. alcohol-based hand rub) to the surface of the hands; and use of soap/solution (plain or antimicrobial) and water (if hands are visibly soiled), followed by patting dry with single-use towels.</td>
</tr>
<tr>
<td>Healthcare facility</td>
<td>Any facility that delivers healthcare services. Healthcare facilities could be hospitals, general practice clinics, dentistry practices, other community-based office practices, day surgery centres, emergency services, domiciliary nursing services, long-term care facilities, Indigenous medical services, alternative health provider facilities and other community service facilities, such as needle exchanges.</td>
</tr>
<tr>
<td>Healthcare workers</td>
<td>All people delivering healthcare services, including students and trainees, who have contact with patients or with blood or body substances.</td>
</tr>
<tr>
<td>Healthcare-associated infections</td>
<td>Infections acquired in healthcare facilities (‘nosocomial’ infections) and infections that occur as a result of healthcare interventions (‘iatrogenic’ infections), and which may manifest after people leave the healthcare facility.</td>
</tr>
<tr>
<td>High level disinfection</td>
<td>Minimum treatment recommended for reprocessing instruments and devices that cannot be sterilised for use in semi-critical sites</td>
</tr>
</tbody>
</table>
### Glossary

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>High-efficiency particulate air (HEPA) filter</strong></td>
<td>An air filter that removes &gt;99.97% of particles &gt; 0.3 microns (the most penetrating particle size) at a specified flow rate of air.</td>
</tr>
<tr>
<td><strong>High-risk patients</strong></td>
<td>Patients with an increased probability of infection due to their underlying medical condition. Often refers to patients in intensive care units, those receiving total parenteral nutrition, and immunocompromised patients.</td>
</tr>
<tr>
<td><strong>Hospital-grade disinfectant</strong></td>
<td>A TGA-registered disinfectant for surfaces for use in healthcare or healthcare-related applications.</td>
</tr>
<tr>
<td><strong>Hypochlorite</strong></td>
<td>A chlorine-based disinfectant.</td>
</tr>
<tr>
<td><strong>Immunocompromised</strong></td>
<td>Having an immune system that has been impaired by disease or treatment.</td>
</tr>
<tr>
<td><strong>Incidence</strong></td>
<td>The number of new events (e.g. cases of disease) occurring in a population over defined period of time.</td>
</tr>
<tr>
<td><strong>Infectious agent</strong></td>
<td>An infectious agent (also called a pathogen or germ) is a biological agent that causes disease or illness to its host. Most infectious agents are microorganisms, such as bacteria, viruses, fungi, parasites and prions.</td>
</tr>
<tr>
<td><strong>Instrument disinfectant</strong></td>
<td>A TGA-registered disinfectant for medical devices.</td>
</tr>
<tr>
<td><strong>Intermediate level disinfection</strong></td>
<td>Minimum treatment recommended for reprocessing instruments and devices for use in non-critical sites, or where there are specific concerns regarding contamination of surfaces with species of myobacteria (e.g. Mycobacterium tuberculosis).</td>
</tr>
<tr>
<td><strong>Invasive procedure</strong></td>
<td>Entry into tissues, cavities or organs or repair of traumatic injuries.</td>
</tr>
<tr>
<td><strong>Key parts</strong></td>
<td>Parts of the procedure equipment or solutions that must remain aseptic throughout clinical procedures, in order to protect the patient from contamination or infection. For example a wound dressing, catheter lubrication, syringe tip, needle etc. In IV therapy, key parts are usually those that come into direct contact with the liquid infusion e.g. needles, syringe tips, exposed central line lumens.</td>
</tr>
<tr>
<td><strong>Key sites</strong></td>
<td>Susceptible open or broken wounds, surgical or intravenous access sites.</td>
</tr>
<tr>
<td><strong>Klebsiella pneumoniae</strong></td>
<td>Gram-negative bacteria frequently responsible for healthcare associated infections of wounds and urinary tract, particularly in immunocompromised patients; may also cause pneumonia.</td>
</tr>
<tr>
<td><strong>Long-term care facilities</strong></td>
<td>A range of residential and outpatient facilities designed to meet the bio-psychosocial needs of persons with sustained self-care deficits.</td>
</tr>
<tr>
<td><strong>Low-level disinfection</strong></td>
<td>An alternative treatment to cleaning alone when devices for use in non-critical sites are reprocessed and when only vegetative bactericidal activity is needed.</td>
</tr>
<tr>
<td><strong>Medical device</strong></td>
<td>A device that is intended for use with humans and used in therapeutic processes, being entered onto the ARTG.</td>
</tr>
<tr>
<td><strong>Methicillin-resistant Staphylococcus aureus (MRSA)</strong></td>
<td>Strains of Staphylococcus aureus that are resistant to many of the antibiotics commonly used to treat infections. Epidemic strains also have a capacity to spread easily from person-to-person.</td>
</tr>
<tr>
<td><strong>Multi-drug resistant organisms (MROs)</strong></td>
<td>In general, bacteria that are resistant to one or more classes of antimicrobial agents and usually are resistant to all but one or two commercially available antimicrobial agents.</td>
</tr>
<tr>
<td><strong>Needle-free devices (also needleless intravascular catheter connectors)</strong></td>
<td>Intravascular connector systems developed to help reduce the incidence of needlestick injury while facilitating medication delivery through intravascular catheters. There are three types of needle-free connectors: blunt cannula (two-piece) systems, one-piece needle-free systems, and one-piece needle-free systems with positive pressure.</td>
</tr>
<tr>
<td><strong>Negative pressure room</strong></td>
<td>A single-occupancy patient-care room used to isolate persons with a suspected or confirmed airborne infectious disease. Environmental factors are controlled in negative pressure rooms to minimise the transmission of infectious agents that are usually transmitted from person to person by droplet nuclei associated with coughing or aerosolisation of contaminated fluids.</td>
</tr>
<tr>
<td>Glossary Term</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------</td>
<td>------------</td>
</tr>
<tr>
<td>P2 respirator</td>
<td>A particulate filter personal respiratory protection device or P2 respirator is a close fitting mask worn for airborne precautions, which is capable of filtering 0.3μm particles. A P2 respirator must comply with AS/NZS 1716:2009.</td>
</tr>
<tr>
<td>Pandemic</td>
<td>An epidemic that is geographically widespread, occurring throughout a region or even throughout the world.</td>
</tr>
<tr>
<td>Patient contact</td>
<td>Involves touching the patient and their immediate surroundings, or performing any procedure on the patient.</td>
</tr>
<tr>
<td>Patient surroundings</td>
<td>All inanimate surfaces that are touched by or in physical contact with the patient (such as bed rails, bedside table, bed linen, invasive devices, dressings, personal belongings and food) and surfaces frequently touched by healthcare workers while caring for the patient (such as monitors, knobs and buttons).</td>
</tr>
<tr>
<td>Patient-care area</td>
<td>The room or area in which patient care takes place.</td>
</tr>
<tr>
<td>Percutaneous injury</td>
<td>An injury that results in a sharp instrument/object, e.g. needle, scalpel, cutting or puncturing the skin.</td>
</tr>
<tr>
<td>Personal protective equipment (PPE)</td>
<td>A variety of barriers used alone or in combination to protect mucous membranes, skin, and clothing from contact with infectious agents. PPE includes gloves, masks, respirators, protective eyewear, face shields, and gowns.</td>
</tr>
<tr>
<td>Phlebitis</td>
<td>Inflammation of the wall of a vein.</td>
</tr>
<tr>
<td>Powered air-purifying respirator (PAPR)</td>
<td>Powered air-purifying respirator (PAPR) devices should conform to AS/NZS 1715 and AS/ANZS 1716, and must only be used by healthcare workers who are trained in their use. The manufacturer’s instructions for cleaning, decontaminating and maintenance must be followed. PAPR may be suitable for healthcare workers with facial hair and those who fail fit testing for P2 respirators.</td>
</tr>
<tr>
<td>Prevalence</td>
<td>The number of events (e.g. cases of disease) present in a defined population at one point in time.</td>
</tr>
<tr>
<td>Procedure</td>
<td>An act of care for a patient where there is a risk of direct introduction of a pathogen to the patient.</td>
</tr>
<tr>
<td>Randomised controlled trial (RCT)</td>
<td>A clinical trial where at least two treatment groups are compared, and non-randomised control trial (NRCT) one of them serving as the control group, and treatment allocation is carried out using a random, unbiased method. A non-randomised controlled trial compares a control and treatment group but allocation to each group is not random. Bias is more likely to occur in NRCT.</td>
</tr>
<tr>
<td>Respiratory hygiene and cough etiquette</td>
<td>A combination of measures designed to minimize the transmission of respiratory pathogens via droplet or airborne routes in healthcare settings.</td>
</tr>
<tr>
<td>Routine</td>
<td>Performed as part of usual practice (as opposed to the use of additional measures in specific circumstances e.g. where invasive procedures are conducted or in the event of an outbreak).</td>
</tr>
<tr>
<td>Sharps</td>
<td>Instruments used in delivering healthcare that can inflict a penetrating injury, e.g. needles, lancets and scalpels.</td>
</tr>
<tr>
<td>Single-use</td>
<td>Single-use means the medical device is intended to be used on an individual patient during a single procedure and then discarded. It is not intended to be reprocessed and used on another patient. Some single-use devices are marketed as non-sterile which require processing to make them sterile and ready for use. The manufacturer of the device will include appropriate processing instructions to make it ready for use.</td>
</tr>
<tr>
<td>Single-use devices</td>
<td>Single-use devices are medical devices that are labelled by the original manufacturer as ‘single use’ and are only intended to be used once. <a href="http://www.tga.gov.au/devices/fs-sudman.htm">http://www.tga.gov.au/devices/fs-sudman.htm</a></td>
</tr>
<tr>
<td>Standard precautions</td>
<td>Work practices that constitute the first-line approach to infection prevention and control in the healthcare environment. These are recommended for the treatment and care of all patients.</td>
</tr>
<tr>
<td>Glossary Term</td>
<td>Definition</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Standard-ANTT</strong></td>
<td>An approach to ANTT used for technically simple aseptic procedures.</td>
</tr>
<tr>
<td><strong>Sterile</strong></td>
<td>Free from all living microorganisms; usually described as a probability (e.g. the probability of a surviving microorganism being 1 in 1 million).</td>
</tr>
<tr>
<td><strong>Sterile technique</strong></td>
<td>Sterile technique aims to eliminate microorganisms from areas and objects, and should be undertaken by all healthcare workers undertaking invasive medical procedures. This includes: ensuring that everything within a defined radius is clean and sterile, or as a minimum subject to high level chemical or thermal disinfection; use of skin antisepsis and sterile personal protective equipment; and reprocessing of instruments between patient uses. Due to the natural multitude of organisms in the atmosphere it is not possible to achieve a true sterile technique for most invasive procedures in a typical hospital environment (even when wearing sterile gloves). Sterile techniques can only be achieved in controlled environments such as a laminar air flow cabinet or a specially equipped theatre. The commonly used term, 'sterile technique' is therefore inaccurate, as practitioners are not actually achieving their stated objective.</td>
</tr>
<tr>
<td><strong>Sterilisation</strong></td>
<td>Use of a physical or chemical procedure to destroy all microorganisms including substantial numbers of resistant bacterial spores.</td>
</tr>
<tr>
<td><strong>Strain</strong></td>
<td>A strain is a genetic variant or subtype of a microorganism (e.g. a virus, bacterium or fungus). Some strains may be more dangerous or difficult to treat than others.</td>
</tr>
<tr>
<td><strong>Surface barrier</strong></td>
<td>Barriers (e.g. clear plastic wrap, bags, sheets, tubing or other materials impervious to moisture) designed to help prevent contamination of surfaces and equipment.</td>
</tr>
<tr>
<td><strong>Surgical hand preparation</strong></td>
<td>The process of eliminating transient and reducing resident flora prior to surgery. This comprises removal of hand jewellery, performing hand hygiene with liquid soap if hands are visibly soiled, removing debris from underneath fingernails and scrubbing hands and forearms using a suitable antimicrobial formulation.</td>
</tr>
<tr>
<td><strong>Surgical masks</strong></td>
<td>Loose-fitting, single-use items that cover the nose and mouth. These include products labelled as dental, medical procedure, isolation and laser masks.</td>
</tr>
<tr>
<td><strong>Surgical-ANTT</strong></td>
<td>An approach to ANTT used for technically complex aseptic procedures.</td>
</tr>
<tr>
<td><strong>Surgical-site infection</strong></td>
<td>An infection at the site of a surgical operation that is caused by the operation.</td>
</tr>
<tr>
<td><strong>Surveillance</strong></td>
<td>Disease surveillance is an epidemiological practice by which the spread of disease is monitored in order to establish patterns of progression. The main role of disease surveillance is to predict, observe and minimise the harm caused by outbreak, epidemic and pandemic situations, as well as increase knowledge as to what factors might contribute to such circumstances.</td>
</tr>
<tr>
<td><strong>Targeted surveillance</strong></td>
<td>A process in which data are collated on the susceptibilities and resistances of disease-causing microbes to various antimicrobial treatments. Targeted surveillance gathers data that is not generated by routine testing: specific species or groups of species are examined in detail to answer important questions that cannot be addressed by passive surveillance.</td>
</tr>
<tr>
<td><strong>Transmission-based precautions</strong></td>
<td>Extra work practices in situations where standard precautions alone may be insufficient to prevent infection (e.g. for patients known or suspected to be infected or colonised with infectious agents that may not be contained with standard precautions alone).</td>
</tr>
<tr>
<td><strong>Vancomycin resistant enterococci (VRE)</strong></td>
<td>Enterococci are Gram-positive bacteria that are naturally present in the intestinal tract of all people. Vancomycin is an antibiotic to which some strains of enterococci have become resistant. These resistant strains are referred to as VRE and are frequently resistant to other antibiotics generally used to treat enterococcal infections.</td>

Abbreviations and Acronyms

ACH  air changes per hour
ACSQHC  Australian Commission on Safety and Quality in Health Care
ADEC  Australian Drug Evaluation Committee
AGREE  Appraisal of guidelines research and evaluation
AICA  Australian Infection Control Association
ANTT  aseptic non-touch technique
ARTG  Australian Register of Therapeutic Goods
AusHFG  Australasian Health Facility Guidelines
AusHFG  Australasian Health Facility Guidelines
BCG  Bacillus Calmette-Guérin
BSI  bloodstream infection
CA-MRSA  community-acquired methicillin-resistant *Staphylococcus aureus*
CAUTI  catheter-associated urinary tract infection
CBIC  Certification Board of Infection Control
cCJD  classical Creutzfeldt-Jakob disease
CDC  Centers for Disease Control and Prevention (US)
CDNA  Communicable Diseases Network Australia
CEO  chief executive officer
CHG  chlorhexidine-impregnated
EPP  exposure-prone procedures
ESBL  extended spectrum beta-lactamase
GPP  good practice point
HAI  healthcare-associated infection
HBeAg  hepatitis B e antigen
HBsAg  HBV surface antigen
HBV  hepatitis B virus
HCV  hepatitis C virus
HEPA  high efficiency particulate air
HIV  human immunodeficiency virus
HTLV-I  human T-cell lymphotropic virus type I
IHI  Institute for Healthcare Improvement (US)
IPC  infection prevention and control
IVD  intravascular device
LAS  laminar airflow filtration
MMR  measles mumps rubella vaccine
MRGN  multi-resistant Gram negative
MRO  multi-resistant organism
MRSA  methicillin-resistant *Staphylococcus aureus*
NaOH  sodium hydroxide
NATA  National Association of Testing Authorities
