Publication approval

These guidelines were approved by the Chief Executive Officer of the National Health and Medical Research Council (NHMRC) on 25 October 2012, under Section 7 of the *National Health and Medical Research Council Act 1992*. In approving these guidelines the NHMRC considers that they meet the NHMRC standard for clinical practice guidelines. This approval is valid for a period of five years.

Presentation of the evidence

Guideline adaption

This guideline is an adaptation of the UK National Institute of Clinical Excellence (NICE) Guideline. Where the NHMRC BPD Guideline Development Committee agreed to update the clinical questions included in the NICE guideline, all papers retrieved by NICE were used as the evidence base from 2001 – 2008. The systematic search was used to update the body of evidence for the NICE questions from 2008 – 2011. The updated searches for the NICE questions were based upon new search strings developed using a combination of:

- a) The searches undertaken in the NICE Guideline
- b) The aims and scope of the NHMRC guideline
- c) The clinical questions and inclusion and exclusion criteria developed by the NHMRC BPD Guideline Development Committee in February 2011, and those of the NICE guideline.

For the 5 new clinical questions (Qu 3, 4, 10, 11, 14) not previously included in the NICE guideline but developed by the NHMRC BPD Guideline Development Committee, a new strategy was undertaken with a search period from 2001 – 2011.

The included papers retrieved from the different search strategies are differentiated in this document using the following terms:

- **Updated search** - used to describe the process of the systematic search of the literature used to update the body of evidence for the NICE questions.
- **NICE Guideline summary** – the summary of evidence from the NICE findings as developed by the NICE guideline group.
- **Summary** – summary of evidence from the updated search or the new strategy as developed by the NHMRC BPD Guideline Development Committee.

How to read the evidence summaries, evidence tables and forest plots

Evidence summaries

An evidence summary is provided for each clinical question including what evidence was available. For some clinical questions, no evidence was identified.

Evidence summaries provide a snapshot of studies addressing each clinical question. For a detailed assessment of each paper's outcomes, quality and relevance, it is essential to read the evidence tables.

Evidence tables

Evidence summaries are accompanied by evidence tables which provide an analysis of each study that met the inclusion criteria, including assessment of study quality.

When reading an evidence table it is common to refer to the highest level of evidence to answer each question and move through the hierarchy of evidence as required. Studies are presented in the tables in order of level of evidence. When two or more studies were classified at the same level of evidence they are ordered by publication date from most recent to least recent.

Each study was assessed using quality checklists appropriate to the type of study design used. Specific Quality Checklists (QC) used and their criteria are outlined in Appendix B (page 19). The results of these assessments have been included against each study in the comments section of the evidence tables.

Two reviewers extracted the data and assessed it using the Quality Checklist (QC) included in Appendix B (page 19).

Evidence statement forms

The committee used the NHMRC Evidence Statement Form to review the body of available evidence with regard to the volume of evidence and its consistency, clinical impact, generalisability and applicability. The evidence was graded according to NHMRC grading criteria. Evidence tables are accompanied by evidence statement forms to provide information on how the committee made judgements on the basis of the body of evidence relevant to specific research questions.

Meta-analysis

In the instance of clinical questions 6, 7 and 9, data from the included studies have been combined statistically to produce summary estimates of effect using the statistical meta-analysis program Comprehensive Meta-Analysis (CMA) 2.0.

Through statistically pooling (meta-analysing), more precise estimates of the effect of the intervention on the important outcomes can be obtained and compared with individual studies considered in isolation. Meta-analysis increases the statistical power of the analysis and may find a statistically significant result where none of the individual studies included in the analysis were found statistically significant when considered in isolation.

Forest plots

The results of the meta-analysis are displayed graphically in forest plots which show the individual results of each study together with the combined meta-analysis result. Forest plots also include the overall risk ratio for that outcome. The results of individual studies are shown as squares centred on each study's point estimate. A horizontal line runs through each square to show each study's 95% confidence interval. The overall estimate from the meta-analysis and its confidence interval are shown at the bottom, represented as a diamond. The centre of the diamond represents the pooled point estimate, and its horizontal tips represent the confidence interval.

Forest plots usually include a "line of 1" (for dichotomous outcomes) and are labelled at the bottom with '*favours the intervention*' or '*favours the comparator*' which assist users to interpret the findings. If the lines showing 95% confidence intervals for individual studies, or the diamond showing the confidence intervals of the pooled relative risk, cross the "line of 1", then the result is not statistically significant.

The forest plot also allows readers to see the heterogeneity among the results of the studies. This can be assessed informally by considering the spread of results and the direction of outcomes for the included studies (i.e. by looking at the square box and line plots). The results or estimates of effects of treatment from separate studies may seem to be very different – in terms of the size of treatment effects or even to the extent that some indicate beneficial and others suggest adverse treatment effects. Such results may occur because of differences between studies (e.g. the patient populations, outcome measures, definition of variables or duration of follow-up).

NHMRC Evidence hierarchy: designations of 'levels of evidence' according to type of research question

Level	Intervention	Diagnostic accuracy	Prognosis	Aetiology	Screening Intervention
I	A systematic review of level II studies	A systematic review of level II studies	A systematic review of level II studies	A systematic review of level II studies	A systematic review of level II studies
II	A randomised controlled trial	A study of test accuracy with: an independent, blinded comparison with a valid reference standard, among consecutive persons with a defined clinical presentation	A prospective cohort study	A prospective cohort study	A randomised controlled trial
III-1	A pseudorandomised controlled trial (i.e. alternate allocation or some other method)	A study of test accuracy with: an independent, blinded comparison with a valid reference standard, among non-consecutive persons with a defined clinical presentation	All or none	All or none	A pseudorandomised controlled trial (i.e. alternate allocation or some other method)
III-2	A comparative study with concurrent controls: <ul style="list-style-type: none"> Non-randomised, experimental trial Cohort study Case-control study Interrupted time series with a control group 	A comparison with reference standard that does not meet the criteria required for Level II and III-1 evidence	Analysis of prognostic factors amongst persons in a single arm of a randomised controlled trial	A retrospective cohort study	A comparative study with concurrent controls: <ul style="list-style-type: none"> Non-randomised, experimental trial Cohort study Case-control study
III-3	A comparative study without concurrent controls: <ul style="list-style-type: none"> Historical control study Two or more single arm study Interrupted time series without a parallel control group 	Diagnostic case-control study	A retrospective cohort study	A case-control study	A comparative study without concurrent controls: <ul style="list-style-type: none"> Historical control study Two or more single arm study
IV	Case series with either post-test or pre-test/post-test outcomes	Study of diagnostic yield (no reference standard)	Case series, or cohort study of persons at different stages of disease	A cross-sectional study or case series	Case series

Clinical Question 1. What can help clinicians identify features of BPD in young people?

NICE Guideline summary

Notes: NICE did not do a systematic search on this clinical question but the question was addressed by a team of special advisors who identified a number of clinical features from Chanen (2007):

- Frequent suicidal/self harming behaviours
- Marked emotional instability
- Increasing intensity of symptoms
- Multiple comorbidities
- Non response to established treatments for current systems
- High level of functional impairment
- Chanen et al. (2008)¹ also note a range of symptoms associated with early detection: Disruptive behaviour disorders in childhood or adolescence, depressive symptoms predict young adult personality disorders; substance use disorders during adolescence predict young adult BPD. Symptoms of BPD in youth are as reliable and valid as those in adults and most likely predictors of adult BPD

Updated search

No further papers that met the inclusion criteria were identified in an updated search.

¹ Screening for borderline personality disorder in outpatient youth. Journal of Personality Disorders, 22(4), 353-364.

Clinical Question 2. Are there tools/assessments that could be used?

NICE Guideline summary

Notes: NICE did not do a systematic search on this clinical question but the question was addressed by a team of special advisors who refer to Chanen (2008) outlined below for ease of reference.

Ref, Country	Study Design/ Level of Evidence	N (n)	Participants Age Gender Diagnosis Other	Intervention	Comparison	Outcomes	Measure/s	Length of follow-up	Effect Size	Comments
Chanen at al (2008). Screening for borderline personality disorder in outpatient youth. Journal of Personality Disorders, 22(4), 353-364. Australia	Validity study – Level II or Level III-2	101	Mean age 18.8 (15- 25yo) 73% female 22% met criteria for BPD Most common Axis I: 55% mood disorders, 51% anxiety disorders, 21% substance dependence, 19% eating disorders. Outpatients in a youth mental health facility.	MSI-BPD BPQ BPD items from IPDESQ BPD items from SCID-II- PQ-BPD	SCID-II (full)	All 4 instruments performed similarly. BPQ significantly outperformed MSI BPQ preferred overall for best balance of sensitivity, specificity, negative and positive predictive value, diagnostic accuracy (0.85), kappa, internal consistency and test-retest reliability but is lengthy to administer (15 mins) SCID-II-PQ-BPD best of the shorter instruments.	NA	NA	NA	Authors conclude in abstract (but not clearly evidenced in body of paper) that screening is effective, but not a replacement for clinical diagnosis Blinding not fully described.

Updated search

No further papers that met the inclusion criteria were identified in an updated search.

Clinical Question 3. *What are the risk factors for BPD?*

NICE Guideline summary

This was a new question – No NICE summary is available

Updated search

Summary

The study of risk factors is methodologically complex. In this search only prospective population cohort studies, or prospective or retrospective cohort studies with matched control groups, were included. Three studies were identified that met the criteria and specifically examined risk factors for the development of BPD. The three studies show that a number of early childhood variables increase risk of developing BPD including parental socio-economic status, a history of trauma or stressful life events, poor or inconsistent parenting and psychiatric comorbidity.

Reference	Summary	Comments
Cohen 2008	The main finding was that low SES (low income, low education level, low-status occupation) showed robust modest predictive effects of BPD even when other predictive risk factors were taken into account. Other substantial cumulative effects included: being female, cumulative trauma history (history of child abuse or neglect, parental alcohol or substance abuse or dependence, parental arrest/imprisonment, parental death, death of a spouse, death of a child, army combat experience, close personal exposure to violent death, or family suicide), stressful life events, IQ, poor parenting and comorbidity.	Large prospective sample, but most measures were mother-reported, although standardised, and some subjective and collected retrospectively.
Fischer 2002	A significantly greater percentage of hyperactive children than control children were diagnosed with BPD at follow-up (3% of 14%) suggesting that hyperactivity in childhood is a risk factor for BPD in early adulthood.	Small prospective cohort study with matched control originally assessed when they were between 4-12 yo and reassessed in this paper when they were 19-25 yo.
Widom 2009	Abused or neglected children were matched with non-victimised children on age, sex, ethnicity and social class and followed up into young adulthood. Rates of BPD in the controls were higher than in the community. Last finding about parents divorced or separated not clear from the paper but stated in the conclusions.	Large prospective cohort study with two waves of follow-up. First interview 1989-95 (29 yo). Second interview 2000-2002 (40 yo) data analysis on 2nd interview.

Notes: Review of the stability of BPD on page 349-355 of the NICE guidelines is also recommended.

Clinical Question 4. *What preventative interventions are available to reduce the incidence of BPD? (as a primary or secondary outcome)*

NICE Guideline summary

This was a new question – No NICE summary is available

Updated search

No papers that met the inclusion criteria were identified in the search.

Clinical Question 5. What interventions and care processes are effective in improving outcomes or altering the developmental course for people aged under 18 years with borderline symptoms or putative BPD? (that is, would meet diagnosis if over 18)

NICE Guideline summary

In relation to treatment for young people, the NICE guideline development committee asked the following clinical question: What interventions and care processes are effective in improving outcomes or altering the developmental course for people under the age of 18 years with borderline personality disorder or borderline symptoms? To address this question, the literature of adults with borderline personality disorder was scanned to ascertain whether any studies had been conducted with young people. One study was identified, of Cognitive Analytic Therapy (CAT) (Chanen, 2008), but there was no effect for CAT compared with manualised 'good practice' other than for reducing self-harm and general functioning. No study of a pharmacological intervention was identified in young people aged under 18 years. This is not surprising because not only does no drug have marketing authorisation for the treatment of people with borderline personality disorder, but also few psychotropic drugs have marketing authorisation for young people aged under 18 for any indication. In the absence of high-quality evidence, the NICE guideline development committee and its special advisors agreed that both the general principles and the recommendations for treatment for adults described elsewhere in this guideline could be applied to young people. Section 9 in the NICE guidelines outlines its findings on young people.

Updated search

Summary

Two papers were identified, one examining Cognitive Analytic Therapy (CAT) and one examining emotional regulation training. CAT showed some improvement over treatment as usual but emotional regulation training did not.

				responsibility for their behaviour and realize they have a choice in how to (re)act when emotionally distressed.		measure, we found a significant interaction effect on the adolescents' MERLC subscale internal locus of control ($F [1, 24] = 9.16; p = 0.006$). Adolescents in the ERT group reported an improvement in their feeling of having control over their emotions, whereas the adolescents in the TAU alone group reported a decrease of internal locus of control. The secondary outcome measures for the adolescents showed no significant effect between groups, measured by the YSR, internalizing and externalizing subscales (YSRintern $F [1, 23] = 0.32; p = 0.58$; YSRextern $F [1, 24] = 0.06; p = 0.82$).				completers only 1.10=E 2.1 = (+)

Clinical Question 6. For people with BPD, which treatments are associated with improvement in mental state and quality of life, reduction in self-harm, service use, and risk-related behaviour, and/or improved social and personal functioning while minimising harms?

NICE Guideline summary

The NICE guideline did not match questions with recommendations specifically. This question appears to be an umbrella question for NICE Questions 4a-c, so there is no specific NICE guideline summary.

Updated search

The findings for Q7, Q9, Q10 and Q11/13 were used to develop the summary for this question.

Summary

Caution is required in interpreting this summary as:

- a) there is a mix of pharmacotherapy and psychological therapy studies to answer this question
- b) there were only a few studies for each specific treatment, often multiple studies of the same treatment from the same research group
- c) these data are from the updated search from 2008-2011 only and the summary does not take into account previous work in the area. Some therapies that have been subject to RCT work earlier than others and the summary does not reflect that.

Mental state

In general psychotherapy appeared to have a positive effect on mental state, including anger, depression and anxiety. In many cases the treatment condition did only as well as the control condition, which was most commonly treatment as usual. Psychodynamic/analytic therapies, especially mentalisation, appeared more consistently to have a moderate to large impact on these measures than other therapies. A range of pharmacotherapies had moderate to large impacts on mental state measures, in particular mood stabilisers/anticonvulsants showed the most consistent responses. Antipsychotics showed mixed effects. Antidepressants had little effect on mental state except in the short term.

QoL

Relatively few studies specifically measured quality of life. Where QoL was measured, most psychological treatments improved quality of life, even those that did not have an impact on clinical measures. QoL was not generally reported in pharmacotherapy studies.

Self-harm and risk behaviours

Most treatments had an impact on suicide and self-harming behaviours, including treatment as usual or general psychiatric management. Mentalisation-based treatment appeared to have the greatest impact on these measures compared to control conditions. Many studies measured suicide and self-harm within measures of overall BPD symptoms and were not always reported separately. There is some evidence that olanzapine can increase self-harming behaviours.

Service utilisation

Relatively few studies specifically measured service utilisation. In general psychological treatments had an impact on hospital utilisation, reducing crisis utilisation and increasing use of/engagement in therapy.

Personal & social functioning

Studies measured included a number of different measures that might fit into this broad category. Most psychological therapies showed improved personal and social functioning, including treatment as usual- type conditions. Effects of pharmacotherapy on personal and social functioning were mixed and not consistent enough to draw conclusions.

Summary table

Notes: Studies that address this question are included in Q7-9 and repeated here by outcome. Studies that potentially answer this question but are related to specific populations (i.e., those with co-occurring conditions) are detailed in Q11 and 13 evidence tables. A summary of the evidence for this table is available in a separate document.

mentalization-based treatment versus structured clinical management for borderline personality disorder. American Journal of Psychiatry, 166(12), 1355-1364. UK			<p>Diagnosis - All participants were assessed using the Structured Clinical Interview for DSM-IV (SCID-I and SCID-II).</p> <p>Ethnicity - White British/European and Black African/Afro-Caribbean MBT: 76.1%, SCM: 68.3%; Black African/Afro-Caribbean MBT: 15.5%, 20.6% Other Chinese/Turkish Pakistani 8.5%, 11.1%</p> <p>Inclusion criteria were 1) diagnosis of BPD, 2) suicide attempt or episode of life-threatening self-harm within last 6 months, and</p>	weekly combined individual and group psychotherapy provided by two different therapists. MBT is a psychodynamic treatment rooted in attachment and cognitive theory. It requires limited training with moderate levels of supervision for implementation by generic mental health professionals. It aims to strengthen patients' capacity to understand their own and others' mental states in attachment contexts in order to	context representing best current clinical practice. Practitioners received equivalent supervision. Crisis plans were developed collaboratively within each treatment team for all patients. SCM therapists focused on support and problem solving.	<p>clinical management recommended by NICE significantly benefits patients with BPD. Both conditions were associated with substantially reduced suicidality, self-harm, and hospitalization and improvement on measures of symptoms and social and interpersonal functioning by the end of treatment. The rate of improvement in both groups was higher than spontaneous remission of symptoms of BPD. Although patients in both groups made statistically significant improvements, MBT was associated with greater improvements than SCM for most outcomes.</p> <p>Detail: Suicidal behaviour: Six-month periods free of suicidal</p>	<p>indicated by 1) suicide attempt, 2) life-threatening self-harm, or 3) hospital admission. Hospital admission was included because patients are primarily offered inpatient care in anticipation of suicide attempts and severe self-harm</p> <p>Secondary outcome: were independently rated Global Assessment of Functioning (GAF) scores at the beginning and end of treatment and self-reported psychiatric symptoms, social and interpersonal functioning, and</p>	6, 12, and 18 months.	<p>0.62 (0.28, 0.97)</p> <p>Interpersonal distress, d = 0.95 (0.59, 1.3)</p> <p>Social adjustment problems, d = 0.72 (0.37, 1.06)</p> <p>Symptom distress, d = 0.67 (0.33, 1.02)</p> <p>Depression, d = 0.45 (0.1, 0.79)</p> <p>Hospital admissions, suicidal and self-injurious episodes, d = -0.72 (-1.07, -0.37)</p> <p>Length of hospitalisation, d = -0.43, (-0.78, -0.09)</p> <p>Medication use, d = -0.58, (-0.93, -0.24)</p> <p>Psychiatric hospitalisation, d = -0.53, (-0.88,</p>	<p>on procedures.</p> <p>QC</p> <p>1.1=A</p> <p>1.2=A</p> <p>1.3=B</p> <p>1.4=F</p> <p>1.5=A</p> <p>1.6=A</p> <p>1.7=A</p> <p>1.8= 0%</p> <p>1.9= A</p> <p>1.10=F</p> <p>2.1 = (+)</p>

						interpersonal relationships ($p < .009$), impulsivity ($p < 0.01$), and affective instability ($p = 0.02$) which increased over time ($p < 0.001$ for all domains). Neither type of therapy nor duration of therapy had effects on: abandonment, parasuicidal behaviour, paranoid ideation, and identity.				
Bos, E.H., Van Wel, E.B., Appelo, M.T., & Verbraak, M.J. (2010). A randomized controlled trial of a Dutch version of systems training for emotional predictability and problem	RCT Level II Randomization was done separately at each location.	N=79 TX (n = 42) C (n = 37)	Between 8 and 12 subjects were included in each group for the Treatment group. If at the time of randomisation , an insufficient number of participants were assigned to a group, the remaining spots were randomly assigned to	Systems Training for Emotional Predictability and Problem Solving (STEPPS) + individual treatment Group treatment; it combines skills training with general CBT elements and has a strong systems component;	Treatment as usual (TAU) The STEPPS groups began simultaneously with a group of patients that started TAU. The control condition was TAU, i.e., the standard treatment for BPD offered at the participating sites. This treatment	Summary: Moderate to large effect sizes were seen for symptom variables and psychological quality of life at T2. At T3, moderate effects on symptoms were still present, while also moderate effects on physical, social and overall quality of life could be observed. More than TAU, STEPPS plus limited adjunctive individual therapy reduced symptomatology and	Primary efficacy measures included general psychiatric and BPD-specific symptoms, measured with the Symptom Checklist-90 total score (SCL-90) and the Borderline Personality Disorder checklist-40 total score (BPD-40) respectively.	Pre-treatment assessments (T1) took place following randomization, just before the start of the intervention. Post-treatment assessments (T2) were done after the final weekly session of	Effect sizes (non-standardised): Primary outcomes: Estimated mean differences at the end of treatment (T2), adjusted for differences at T1, were: SCL-90, -47.0 (95% CI, -78.2 to -15.9, $p = 0.003$); BPD-40, -18.7 (95% CI, -31.6 to -5.8, $p = 0.005$). At 6 mth follow-up (T3), the differences	Raters were not blind and interrater reliability was not assessed for the BPDSI-IV. Intention to treat analysis was completed but yielded similar results to the per-protocol

<p>solving for borderline personality disorder. Journal of Nervous and Mental Disease, 198(4), 299-304.</p> <p>The Netherlands</p>			<p>subjects who did not meet full BPD criteria (these participants were not included in this analysis).</p> <p>Age mean (SD) Treatment 32.9 (5.6) Control 31.8 (9.2)</p> <p>Gender – female (n, %) Treatment 35, 83.3% Control 33, 89.2%</p> <p>Diagnosis BPD confirmed by administering the BPD modules from the Dutch versions of the Personality Diagnostic Questionnaire and the Structured Clinical Interview for</p>	<p>family members and significant others are actively involved in the program.</p> <p>The Dutch version of the STEPPS group program involves 18 weekly sessions and a single follow-up session 3 to 6 months after the conclusion of the program. The program has 3 main components: (1) psychoeducation about BPD; (2) emotion management skills training; and (3) behaviour management skills training. STEPPS is system-based in that friends</p>	<p>consisted of individual therapy from a psychotherapist, psychologist, or psychiatric nurse, offered every 1 to 4 weeks. STEPPS-related treatments like DBT or family groups for family members of the patients were not allowed. In both conditions, the main treatment could be supplemented with (medication) contacts with a psychiatrist, social worker, or other health care professional.</p>	<p>improved quality of life, also in the longer run. STEPPS was not superior to TAU in reducing impulsive and parasuicidal behaviours, but this may be explained by the low base rate of these behaviours in our sample. It may also be that a more intensive treatment, such as DBT, is required to find differential effects on these behaviours. The merit of the STEPPS program is that it is relatively easily learned and implemented, and nevertheless improves BPD treatment in a number of ways. Further research to compare this treatment with other effective treatments is warranted. Importantly, this RCT on STEPPS is the first done by others than its developers.</p> <p>Detail: Scores on the</p>	<p>Secondary outcome measures included impulsive and parasuicidal behaviour, and quality of life. Impulsive and parasuicidal behaviour were assessed using 2 subscales of the Borderline Personality Disorder Severity Index-IV (BPDSI-IV). The impulsivity subscale contains 11 items reflecting potentially harmful impulsive behaviours (e.g., gambling, reckless driving, binge eating). The parasuicide subscale contains 13 items reflecting self-mutilating parasuicidal behaviours and suicidal</p>	<p>the STEPPS program (mean 23.9 ±3.6 weeks after T1). Follow-up assessments (T3) took place approximately 6 months after T2 (mean 25.7 ±4.2 weeks after T2). Outcome measures were assessed on all 3 occasions</p>	<p>were smaller but still significant: SCL-90, -38.4 (95% CI, -67.1 to -9.6, p =0.009); BPD-40, -14.7 (95% CI, -26.6 to -2.8, p =0.016).</p> <p>Secondary outcomes: In the domain of Psychological Health, STEPPS scores were higher than TAU scores particularly at T2 (estimated mean difference adjusted for T1 score: 2.08 [95% CI, 0.76 –3.41, p =0.002]); at T3, this difference was reduced to 0.91 (95% CI, -0.32–2.15, p =0.146). With respect to Overall Quality of Life and General Health, Physical Health and Social Relationships, STEPPS scores were significantly higher than TAU</p>	<p>analysis so only the per-protocol analysis was presented. The comparability of treatment between sites and the comparability between different therapists was not assessed.</p> <p>QC</p> <p>1.1=A 1.2=A 1.3=B 1.4=F 1.5=A 1.6=A 1.7=B 1.8=28.9% (TX) and 13.2% (C) 1.9= 3 1.10=4 2.1 = (+)</p>

				therapy was developed as an adjunct to STEPPS to help consolidate the newly acquired skills and to stimulate their use. It had a structured format, in which the previous STEPPS session was discussed as well as the use of the learned skills in everyday life. The therapy was offered every 2 weeks during the entire study period.		T3. There were no significant differences between the conditions (overall treatment effects). Medication was similar between the groups at baseline and remained stable during follow-up assessment. Over the entire study period, patients in the STEPPS group received 15 STEPPS group sessions on average, and had a mean of 8 contacts with their individual therapist. TAU-patients had a mean of 9 individual contacts with their main therapist. In addition to these study treatment contacts, TAU-patients reported to have had 31 ambulatory therapy contacts on average with other mental health care workers (e.g., psychiatrists, psychologists, psychiatric nurses,			0.35–2.97, $p = 0.974$). Effect sizes (standardised): Effect sizes for the differences between the treatments at T2: SCL-90, 0.68; BPD-40, 0.68; Psychological Health, 0.96. At T3 effect sizes were: SCL-90, 0.56; BPD-40, 0.53; Overall Quality of life & General Health, 0.61; Physical Health, 0.56; Social Relationships, 0.61.

						social workers). Patients in the STEPPS condition had a mean of 21 additional ambulatory therapy contacts.				
Carter, G.L., Willcox, C.H., Lewin, T.J., Conrad, A.M., & Bendit, N. (2010). Hunter DBT project: Randomized controlled trial of dialectical behaviour therapy in women with borderline personality disorder. The Australian and New Zealand journal of psychiatry, (2), 162-173.	RCT Level II The purpose of the present study was to compare dialectical behaviour therapy (DBT) and the control condition of treatment as usual plus weight list (WL) for DBT (TAU+WL).	N=60 Treatment n= 27 Control n= 33	Age mean (SD): Treatment 24.5 ± 6.12; Control 24.7 ± 6.15 Gender: all female Diagnosis: BPD via clinical interview by a psychiatrist using DSM-IV criteria. To be in the study, needed a history of multiple episodes of deliberate self-harm, at least three self-reported episodes in the preceding 12 months.	Modified DBT: team-based approach including individual therapy, group-based skills training, telephone access to an individual therapist and therapist supervision groups following the model of treatment developed by Linehan et al. The main change to the Linehan et al. model was the telephone access to individual therapists. In the present study	WL + TAU The control condition was a 6-month WL for DBT while receiving TAU (TAU+WL). Subjects, both in the initial DBT group and in the TAU+WL group who came to DBT after 6 months were offered 12 months DBT treatment, although the comparison between groups was restricted to the first 6 months of DBT versus TAU+WL.	Summary: The study found no statistically significant differences between modified DBT and waitlist control/TAU except for some quality of life measures. There were trends towards modified DBT in reductions in hospitalisations, shorter lengths of stay, and days in bed. Authors state: There are several possible explanations given to as to why DBT was not effective in this study: regression to background (pre-baseline) levels, the Hawthorne effect whereby both groups improved because of the effect of being in a study, the potentially powerful effect of being in a 6	The primary outcomes (differences in proportions and event rates) of any deliberate self-harm (DSH) event; general hospital admission for DSH and psychiatric admission for any reason; and mean difference in length of stay for any hospitalization. Secondary outcomes were disability and quality of life measures. Specific measures: Composite International Diagnostic Interview modules:	3 and 6 month follow-up	BDQ days in bed, d=-0.66 (-1.25, -0.07) BDQ days out of role, d= -0.43 (-1.01, 0.15) Days in hospital, d= -0.16 (-0.62, 0.30) No. hospital admissions, d= -0.22 (-0.68, 0.24) No. hospital presentations without admission, d= 0.03 (-0.43, 0.49) No. self-harm episodes in previous 3 mths, d= -0.18 (-0.64, 0.28) WHOQOL-BREF Environmental domain, d= 0.43 (-0.14, 0.99) WHOQOL-BREF Physical domain, d= 0.69 (0.11, 1.27)	Very clear on methods of randomisation and concealment (sealed envelopes). Randomization occurred after baseline assessment. Hospitalisation data was intention to treat but rest was per-protocol. Large discrepancy in drop outs between groups.

				1 study, Carbamazepine - 2 studies, Lithium – 1 study, Valproate – 3 studies, Lamotrigine- 1 study, Topiramate - 3 studies		neuroleptics Detail: Antipsychotics have a moderate effect on cognitive-perceptual symptoms. Antipsychotics have a moderate to large effect on anger. Antidepressants have no significant effect on impulsive-behavioural dyscontrol and depressed mood. Antidepressants have a small but significant effect on anxiety and anger. Mood stabilizers have a very large effect on impulsive behavioural dyscontrol. Mood stabilizers have a very large effect on anger. Mood stabilizers have a very large effect on anxiety. Mood stabilizers have a moderate effect on depressed mood. Mood lability as an outcome measure was seldom assessed.			Mood stabilizers have a very large effect on impulsive-behavioural dyscontrol (6 PC-RCTs; SMD = 1.51) and anger (7 PC-RCTs; SMD = 1.33), a large effect on anxiety (3 PC-RCTs; SMD = 0.80), but a moderate effect on depressed mood (5 PC-RCTs; SMD = 0.55). Mood stabilisers have a more pronounced effect on global functioning (3 PC-RCTs; SMD = 0.79) than antipsychotics have (5 PC-RCTs; SMD = 0.37).	

Ref, Country	Study Design/ Level of Evidence	N (n)	Participants Age Gender Diagnosis Other	Intervention	Comparison	Outcomes	Measure/s	Length of follow-up	Effect Size	Comments
						<p>Mood stabilizers have a more pronounced effect on global functioning than have antipsychotics. The effect of antidepressants on global functioning is negligible. The review suggests that atypical antipsychotics do not outperform the classic neuroleptics. With respect to impulsive-behavioural dyscontrol, the prevalent use of antidepressants (SSRIs) is not validated by this meta-analysis, nor is the second step of adding a traditional antipsychotic drug. Modern mood stabilizers seem to deserve a more prominent position. Prescribing SSRIs as first and second steps in the treatment of affective dysregulation seems out-dated since</p>

Stoffers, J., Völm, B.A., Rücker, G., Timmer, A., Huband, N., Lieb, K. (2010) Pharmacological interventions for borderline personality disorder. Cochrane Database of Systematic Reviews. 16(6) Germany.	Cochrane Systematic Review Level 1	Study samples ranged from n = 16 to 314 in size. In total, the included studies provided data from 1742 patients.	Adult patients with a formal diagnosis of BPD according to DSM criteria. The studies were conducted in either the USA (14 studies) or in Western European countries (12 studies) 5 in Germany and/or Austria, two each in the UK and Spain, and one each in Belgium, Ireland and the Netherlands. There were two international multicentre trials. One took place in 13 study centres in the USA, South America, and Eastern	Any drug or a defined combination of drugs administered on a long-term basis (i.e. not only in case of crisis only) with the intention to treat BPD pathology.	Comparison treatments were classified in four categories: • placebo; • active comparator drug; • combination of drugs; • combined treatment, i.e. drug plus concomitant psychotherapeutic treatment or counselling.	Summary: Total BPD severity was not significantly influenced by any drug. There was little evidence for effectiveness of antidepressants. There was little effect of antipsychotics but olanzapine may increase self-harming, weight gain Detail: First-generation antipsychotics (flupenthixol decanoate, haloperidol, thiothixene); second-generation antipsychotics (aripirazole, olanzapine, ziprasidone), mood stabilisers (carbamazepine, valproate semisodium, lamotrigine, topiramate), antidepressants (amitriptyline, fluoxetine, fluvoxamine,	Primary outcomes Overall BPD severity Severity of single BPD criteria according to DSM (avoidance of abandonment, dysfunctional interpersonal patterns, identity disturbance, impulsivity, suicidal ideation, suicidal behaviour, self-mutilating behaviour, affective instability, feelings of emptiness, anger, psychotic paranoid symptoms, dissociative symptoms) Secondary outcomes Depression	Variable	Altogether, 28 RCTs have been included, covering 22 different comparisons in ten comparison categories. In the presence of the multitude of different comparisons and outcome variables, most results are based on single study findings only. The study sample sizes were rather small, and ranged, with exception of two large trials (Schulz 2007; N= 314; Zanarini 2007; N of patient data used here: 301), between 16 (Hollander 2001) and 108 (Soloff 1993; divided into three groups). Therefore, the	Results are mostly based on single study effect estimates. Long-term use of these drugs has not been assessed. Conclusions have to be drawn carefully in the light of several limitations of the RCT evidence that constrain applicability to everyday clinical settings (among others, patients' characteristics and duration of

			41 yrs. Studies were conducted among patients who suffered from other types of aggression, including that in BPDs.	aged between 20 and 35 yrs who were more susceptible to BPD than men and STAXI was used as the primary outcome measure. Study 2 – This study conducted a directed study for BPD in males wherein the same standards (above) as the previous study in females were applied. There were 22 subjects each in the topiramate and placebo arms. Study 3 – This was a 10-week study, which enrolled 64 subjects, and		by -2.93 (-3.49 to -2.37), especially in female BPD patients. 'Anger In' reduced more or less uniformly across the studies by -1.43 (-1.84 to -1.03). 'Anger Out' decreased by -2.8 (-3.19 to -2.42). This effect was minimal among the male BPD patients. Anger Control uniformly increased across the four studies by 2.32 (2.00-2.64). There is sufficient evidence to suggest that topiramate is significantly effective in stabilizing the "trait anger" while reducing the "state anger." "Anger Out" and "hostility" were significantly reduced. "Anger In" was the feature that was the least affected, although this was significant. This suggests that topiramate is	over time. The Anger Expression and Anger Control scales assess relatively independent anger-related traits: (i) expression of anger toward other persons or objects in the environment (Anger-Out), (ii) holding in or suppressing angry feelings (Anger-In) and (iii) controlling angry feelings by preventing the expression of anger toward other persons or objects in the environment or controlling suppressed angry feelings by calming down or cooling off (Anger Control). Individuals rate themselves on			females. The study duration was generally only 8-10 weeks, which reduced the incidence of adverse effects and the dropout rate. Bellino, S., Rinaldi, C., Bogetto, F. (2010) Adaptation of interpersonal psychotherapy to borderline personality disorder: A comparison of combined therapy and single pharmacotherapy. Canadian Journal of Psychiatry. 55(2), 74-81. Italy	RCT Level II	N= 55 enrolled n=44 analysed	55 participants (18 males and 37 females) with DSM-IV-TR diagnosis of BPD were recruited from patients attending the Service for Personality Disorder of the Unit of Psychiatry, Department of Neuroscience, University of Turin. Mean age of 25.8 yrs in medication-only group and 26.2 yrs in combined therapy group; 62% previous hospitalizations; 27%	28 patients received fluoxetine 20 mg to 40 mg daily (see control group for schedule) plus IPT-BPD. IPT-DBT consisted of weekly, manualised sessions lasting 1 hour. Patients in the combined therapy group were treated by a psychotherapist who was not the psychiatrist prescribing the medication and who had 5 yrs of experience practicing IPT. The	27 patients received fluoxetine 20 mg to 40 mg daily plus clinical management consisting of a fortnightly clinical review of 15-20 minutes duration. Initially, fluoxetine was prescribed at a fixed dosage of 20 mg daily with the opportunity to increase the dosage to 40 mg daily beginning in week 2, depending on clinical judgment. Treatment lasted 32 weeks.	Summary: Small sample size limits ability to draw strong conclusions but results suggest that combined therapy was superior to monotherapy in relieving anxiety, improving functioning and alleviating the severity of some symptoms of BPD during the 32 weeks of the trial. Detail: Of 55 subjects, 11 (20%) dropped out (6 in medication-only, 5 in combined therapy). Only treatment completers (n=44) were included in the analysis. Using a univariate General Linear Model to calculate the effects of 1) duration of treatment and 2) the type of treatment on each assessment scale score, only duration of treatment had a statistically significant effect on global functioning, depressive symptoms and social and occupational functioning (p<0.001), while both treatments alleviated symptoms of depression and improved global functioning. Combined therapy was superior to medication-only in alleviating anxiety symptoms (p<0.001). Combined therapy was significantly superior to	Depression (Hamilton Depression Rating Scale) Anxiety (Hamilton Anxiety Rating Scale) Quality of life (SAT-P satisfaction profile) Global functioning (CGI Clinical Global Impression Scale) Social and occupational functioning (SOFAS) BPD symptoms severity and frequency (BPD-SI)	Treatment lasted 32 weeks.	Not reported	No Intention to treat analysis – only analysed data for completers (i.e. 44 of 55 enrolled) and potential attrition bias due to lack of compliance was not addressed. Combined therapy was not compared with IPT alone. QC 1.1=A 1.2=C 1.3=B 1.4=D 1.5=B 1.6=B 1.7=B 1.8= 20% 1.9=D

			were those who had recently received psychotherapy or pharmacotherapy, and current substance abusers.							
Bos, E.H., Van Wel, E.B., Appelo, M.T., & Verbraak, M.J. (2010). A randomized controlled trial of a Dutch version of systems training for emotional predictability and problem solving for borderline personality disorder. Journal of Nervous and Mental	RCT Level II Randomization was done separately at each location.	N=79 TX (n = 42) C (n = 37)	Between 8 and 12 subjects were included in each group for the Treatment group. If at the time of randomisation, an insufficient number of participants were assigned to a group, the remaining spots were randomly assigned to subjects who did not meet full BPD criteria	Systems Training for Emotional Predictability and Problem Solving (STEPPS) + individual treatment Group treatment; it combines skills training with general CBT elements and has a strong systems component; family members and significant others are	Treatment as usual (TAU) The STEPPS groups began simultaneously with a group of patients that started TAU. The control condition was TAU, i.e., the standard treatment for BPD offered at the participating sites. This treatment consisted of individual	Summary: Moderate to large effect sizes were seen for symptom variables and psychological quality of life at T2. At T3, moderate effects on symptoms were still present, while also moderate effects on physical, social and overall quality of life could be observed. More than TAU, STEPPS plus limited adjunctive individual therapy reduced symptomatology and improved quality of life, also in the longer run. STEPPS was not superior to TAU in reducing impulsive and parasuicidal behaviours, but this may be explained by the low base rate of these behaviours in our sample. It may also be that a more intensive treatment, such as DBT, is required to find differential effects on these behaviours. The merit of the	Primary efficacy measures included general psychiatric and BPD-specific symptoms, measured with the Symptom Checklist-90 total score (SCL-90) and the Borderline Personality Disorder checklist-40 total score (BPD-40) respectively. Secondary outcome measures included impulsive and parasuicidal behaviour, and quality of life. Impulsive and parasuicidal behaviour were assessed using 2 subscales of the	Pre-treatment assessments (T1) took place following randomization, just before the start of the intervention. Post-treatment assessments (T2) were done after the final weekly session of the STEPPS program (mean 23.9 ±3.6 weeks after T1).	Effect sizes (non-standardised): Primary outcomes: Estimated mean differences at the end of treatment (T2), adjusted for differences at T1, were: SCL-90, -47.0 (95% CI, -78.2 to -15.9, p = 0.003); BPD-40, -18.7 (95% CI, -31.6 to -5.8, p = 0.005). At 6-month follow-up	Raters were not blind and interrater reliability was not assessed for the BPDSI-IV. Intention to treat analysis was completed but yielded similar results to the per-protocol analysis so only the per-protocol analysis was presented.

Disease, 198(4), 299-304. The Netherlands			(these participants were not included in this analysis). Age mean (SD) Treatment 32.9 (5.6) Control 31.8 (9.2) Gender – female (n, %) Treatment 35, 83.3% Control 33, 89.2% Diagnosis BPD confirmed by administering the BPD modules from the Dutch versions of the Personality Diagnostic Questionnaire and the	actively involved in the program. The Dutch version of the STEPPS program involves 18 weekly sessions and a single follow-up session 3 to 6 months after the conclusion of the program. The program has 3 main components : (1) psychoeducation about BPD; (2) emotion management skills training; and (3) behaviour management skills training.	therapy from a psychotherapist, psychologist, or psychiatric nurse, offered every 1 to 4 weeks. STEPPS-related treatments like DBT or family groups for family members of the patients were not allowed. In both conditions, the main treatment could be supplemented with (medication) contacts with a psychiatrist, social worker, or other health care	STEPPS program is that it is relatively easily learned and implemented, and nevertheless improves BPD treatment in a number of ways. Further research to compare this treatment with other effective treatments is warranted. Importantly, this RCT on STEPPS is the first done by others than its developers. Detail: Scores on the primary efficacy measures. SCL-90 and BPD-40 symptom scores generally decreased from T1 to T3, and more so in the STEPPS group than in the TAU group. Quality of life scores (WHOQOL-Bref) generally increased from T1 to T3. Overall treatment effects were found for Overall Quality of Life and General Health, Physical Health, and Psychological Health. For Social Relationships the overall treatment effect was a trend, for Environment the overall treatment effect was not significant. In both conditions, the number of patients scoring above the cut-off for ratings for the parasuicide and impulsivity subscales of the BPDSI-IV decreased from T1 to T3. There were no significant differences between the conditions (overall	Borderline Personality Disorder Severity Index-IV (BPDSI-IV). The impulsivity subscale contains 11 items reflecting potentially harmful impulsive behaviours (e.g., gambling, reckless driving, binge eating). The parasuicide subscale contains 13 items reflecting self-mutilating Parasuicidal behaviours and suicidal thoughts and attempts. Quality of life was measured with the World Health Organization Quality of Life Assessment-Bref (WHOQOL-Bref)	Follow-up assessments (T3) took place approximately 6 months after T2 (mean 25.7 ±4.2 weeks after T2). Outcome measures were assessed on all 3 occasions	(T3), the differences were smaller but still significant: SCL-90, -38.4 (95% CI, -67.1 to -9.6, p = 0.009); BPD-40, -14.7 (95% CI, -26.6 to -2.8, p=0.016). Secondary outcomes: In the domain of Psychological Health, STEPPS scores were higher than TAU scores particularly at T2 (estimated mean difference adjusted for T1 score: 2.08 [95% CI, 0.76 – 3.41, p = 0.002]); at T3, this	The comparability of treatment between sites and the comparability between different therapists was not assessed. y disorder. Journal of Nervous and Mental Disease, 198(4), 299-304. The Netherlands			meet full BPD criteria (these participants were not included in this analysis). Age mean (SD) Treatment 32.9 (5.6) Control 31.8 (9.2) Gender – female (n, %) Treatment 35, 83.3% Control 33, 89.2% Diagnosis BPD confirmed by administering the BPD modules from the Dutch versions of the Personality Diagnostic	The Dutch version of the STEPPS group program involves 18 weekly sessions and a single follow-up session 3 to 6 months after the conclusion of the program. The program has 3 main components: (1) psychoeducation about BPD; (2) emotion management skills training; and (3) behaviour management skills training. STEPPS is system-based in that friends and relatives of the patients are explicitly involved in the program for support and reinforcement of the newly learned skills (the “support	psychotherapist, psychologist, or psychiatric nurse, offered every 1 to 4 weeks. STEPPS-related treatments like DBT or family groups for family members of the patients were not allowed. In both conditions, the main treatment could be supplemented with (medication) contacts with a psychiatrist, social worker, or other health care professional.	intensive treatment, such as DBT, is required to find differential effects on these behaviours. The merit of the STEPPS program is that it is relatively easily learned and implemented, and nevertheless improves BPD treatment in a number of ways. Further research to compare this treatment with other effective treatments is warranted. Importantly, this RCT on STEPPS is the first done by others than its developers. Detail: Scores on the primary efficacy measures. SCL-90 and BPD-40 symptom scores generally decreased from T1 to T3, and more so in the STEPPS group than in the TAU group. Quality of life scores (WHOQOL-Bref) generally increased from T1 to T3. Overall treatment effects were found for Overall Quality of Life and General Health, Physical Health, and Psychological Health. For Social Relationships the overall treatment effect was a trend, for Environment the overall treatment effect was not significant.	behaviour, and quality of life. Impulsive and parasuicidal behaviour were assessed using 2 subscales of the Borderline Personality Disorder Severity Index-IV (BPDSI-IV). The impulsivity subscale contains 11 items reflecting potentially harmful impulsive behaviours (e.g., gambling, reckless driving, binge eating). The parasuicide subscale contains 13 items reflecting self-mutilating, parasuicidal behaviours and suicidal thoughts and attempts. Quality of life was measured with the World Health Organization Quality of Life Assessment-Bref	23.9 ±3.6 weeks after T1). Follow-up assessments (T3) took place approximately 6 mths after T2 (mean 25.7 ±4.2 weeks after T2). Outcome measures were assessed on all 3 occasions	=0.009); BPD-40, -14.7 (95% CI, -26.6 to -2.8, p =0.016). Secondary outcomes: In the domain of Psychological Health, STEPPS scores were higher than TAU scores particularly at T2 (estimated mean difference adjusted for T1 score: 2.08 [95% CI, 0.76 –3.41, p =0.002]); at T3, this difference was reduced to 0.91 (95% CI, -0.32–2.15, p =0.146). With respect to Overall Quality of Life and General Health, Physical Health and Social Relationships, STEPPS scores were significantly higher than TAU scores only at T3 (estimated differences 1.80 [95% CI, 0.30 –	was presented. 									Olanzapine had more weight gain than fluoxetine SMD 0.98 (0.20, 1.76), and more mild sedation RR 3.50 (1.23, 9.92). No significant effect sizes reported for any other drug vs. drug comparisons	
Leiberich, P., Nickel, M.K., Tritt, K., & Gil, F.P. (2008). Lamotrigine treatment of aggression in female borderline patients, part ii: An 18-month follow-up. Journal of Psychopharmacology, 22(7), 805-808 Germany	RCT Level 2 Double blind RCT, which was broken after the conclusion of final testing in the initial trial (8 weeks) 2:1 randomisation	LG Group n = 18 PG Group n=9	Diagnosis of BPD had to be confirmed by means of an interview with SCID II. Sample was All women. LG Group - mean age 29 PG Group - mean age 28 Participants were outpatients referred through "family doctors".	In the initial 8 week study: Lamotrigine was titrated from 50 mg in the first 2 weeks, to 100 mg in the third week, then to 150 mg in the fourth and fifth weeks and finally to a dose of 200 mg/day in the sixth, seventh and eighth weeks. 200 mg/day lamotrigine continued to be taken up to 18 months.	Placebo initially provided for 8 weeks. After 8 weeks, blind was broken and participants randomised to placebo took neither lamotrigine or placebo.	Summary: Lamotrigine - significant reduction in anger and aggression measured by the STAXI than placebo. No serious side effects but some adverse events during the trial: self-mutilation (LG), attempted suicide (placebo) and weight loss (both) Detail: The LG experienced significantly greater changes than the placebo/Ex-PG on all STAXI scales. No serious side effects were observed. In isolated cases, relatively mild rash, dizziness, headache and nausea were reported. Two subjects from the Ex-PG and one from the LG engaged in self-mutilation and one from the Ex-PG attempted suicide during	State-Trait Anger Expression Inventory (STAXI)	8 wks for initial blinded treatment period. 18 mth long-term follow-up observations were reported, after blinding was discontinued.	Standardised change scores between baseline and follow-up for lamotrigine group: STAXI Anger-In d = -1.41 (95% CI -2.15, -0.67) STAXI Anger-Out d = -2.95 (95% CI -4.16, -1.74) STAXI State Anger d = -4.08 (95% CI -5.68, -2.42) STAXI Trait Anger d = -3.98 (95% CI -5.55, -2.42) Weight d = -0.12 (95% CI -0.65, 0.41) Standardised change scores between baseline and follow-up for	The study was limited in sample size with particularly high drop out in the former control group and also limited due to the discontinuation of blinding after 8 weeks of treatment. Stoffers, J., Völlm, B.A., Rücker, G., Timmer, A., Huband, N., Lieb, K. (2010) Pharmacological interventions for borderline personality disorder. Cochrane Database of Systematic Reviews. 16(6) Germany.	Cochrane Systematic Review Level 1	Study samples ranged from n = 16 to n = 314 in size. In total, the included studies provided data from 1742 patients.	Adult patients with a formal diagnosis of BPD according to DSM criteria. The studies were conducted in either the USA (14 studies) or in Western European countries (12 studies) 5 in Germany and/or Austria, two each in the UK and Spain, and one each in Belgium, Ireland and the Netherlands. There were two international multicentre trials. One took place in	Any drug or a defined combination of drugs administered on a long-term basis (i.e. not only in case of crisis only) with the intention to treat BPD pathology.	Comparison treatments were classified in four categories: • placebo; • active comparator drug; • combination of drugs; • combined treatment, i.e. drug plus concomitant psychotherapeutic treatment or counselling.	Summary: Total BPD severity was not significantly influenced by any drug. There was little evidence for effectiveness of antidepressants. There was little effect of antipsychotics but olanzapine may increase self-harming, weight gain. Detail: First-generation antipsychotics (flupenthixol decanoate, haloperidol, thiothixene); second-generation antipsychotics (aripirazole, olanzapine, ziprasidone), mood stabilisers (carbamazepine, valproate semisodium, lamotrigine, topiramate), antidepressants (amitriptyline, fluoxetine, fluvoxamine, phenelzine sulfate, mianserin), and dietary supplementation (omega-3 fatty acid) were tested. First-generation antipsychotics were subject to older trials, whereas recent studies focussed on second-generation antipsychotics and mood stabilisers. Data were sparse for individual comparisons, indicating	Primary outcomes: Overall BPD severity Severity of single BPD criteria according to DSM (avoidance of abandonment, dysfunctional interpersonal patterns, identity disturbance, impulsivity, suicidal ideation, suicidal behaviour, self-mutilating behaviour, affective instability, feelings of emptiness, anger, psychotic paranoid symptoms, dissociative symptoms) Secondary outcomes: Depression Anxiety General psychiatric pathology: comprehensive	Variable	Altogether, 28 RCTs have been included, covering 22 different comparisons in ten comparison categories. In the presence of the multitude of different comparisons and outcome variables, most results are based on single study findings only. The study sample sizes were rather small, and ranged, with exception of two large trials (Schulz 2007; N= 314; Zanarini 2007; N of patient data used here: 301), between 16 (Hollander 2001) and 108 (Soloff 1993; divided into three groups). Therefore, the power to detect	Results are mostly based on single study effect estimates. Long-term use of these drugs has not been assessed. Conclusions have to be drawn carefully in the light of several limitations of the RCT evidence that constrain applicability to everyday clinical settings (among others, patients' characteristics and duration of interventio

Bateman, A., & Fonagy, P. (2008). 8-year follow-up of patients treated for borderline personality disorder: Mentalization-based treatment versus treatment as usual. American Journal of Psychiatry, 165(5), 631-638. (follow up from Bateman A, Fonagy P (1999). Effectiveness of partial hospitalization in the treatment of borderline personality	RCT Level II RCT (8 yrs since intervention follow-up – reporting occurrences since the 3 year follow-up).	N=41 T=22 C= 19	Age and gender not reported. Diagnosis: BPD on both Structured Clinical Interview for DSM-III-R and Diagnostic Interview for Borderline Patients. Exclusion: If they met criteria for schizophrenia, bipolar, substance misuse or mental impairment or had evidence of organic brain disorder.	Partial hospitalisation consisting of a long-term psychoanalytically orientated treatment for 18 mths. Metallization based treatment (MBT) individual and group therapy. MBT by partial hospitalization consists of 18-mth individual and group psychotherapy in a partial hospital setting offered within a structured and integrated program provided by a supervised team. Expressive therapy using art and writing groups is included.	Treatment as usual (TAU) consists of general psychiatric outpatient care with medication prescribed by the consultant psychiatrist, community support from mental health nurses, and periods of partial hospital and inpatient treatment as necessary but no specialist psychotherapy.	Summary: MBT had a greater effect than TAU on clinical symptoms, suicide and risk behaviours, service utilisation and general functioning Detail: 23% made suicide attempts in the MBT group (mean attempts 0.5 ± 0.9), contrasted with 74% of the TAU group (mean attempts 0.52 ± 0.48), which was significant. Mean number of emergency room visits and hospital days highly significantly favoured the MBT group, as did the continuing treatment profile. During MBT group therapy, all of the experimental group but only 31% of the TAU group received therapy. Over the 5-year postdischarge period, both groups received around 6 mths of psychological therapy (n.s.). For all other treatments, the TAU group received significantly more input postdischarge—3.6 yrs of psychiatric outpatient	Primary: number of suicide attempts over the whole of the 5 year post-discharge follow-up period. Associated outcomes were service use, including emergency room visits; the length and frequency of hospitalization; continuing outpatient psychiatric care; and use of medication, psychological therapies, and community support. Secondary: 1) symptom status as assessed at a follow-up interview using the Zanarini Rating Scale for DSM-IV borderline personality disorder	2 yrs	Suicide attempts total, $d=1.4$ (0.3, 1.5) Zanarini Rating Scale (ZRS) for BPD: total: $d=1.8$ (0.14, 3.5), affect: $d=1.1$ (0.41, 1.7), cognitive: $d=0.84$ (0.3, 1.4), impulsivity: $d=1.2$ (0.59, 1.9), interpersonal: $d=1.6$ (1, 2.3) GAF, $d=0.75$ (-1.9, 3.4) No. of days of hospitalisation, $d=1.5$ (0.36, 2.7) No. of emergency room visits, $d=1.4$ (0.21, 2.63) No. of yrs of employment, $d=0.94$ (0.29, 1.6) No. of yrs psychiatric outpatient treatment, $d=0.93$ (-4, 1.5)	QC 1.1=A 1.2=B 1.3=B 1.4=B 1.5=B 1.6=A 1.7=A 1.8= 0% and 18% 1.9= C 1.10=F 2.1 = (+)

disorder: a randomized controlled trial. Am J Psychiatry, 156, 1563–1569)				Crises are managed within the team; medication is prescribed according to protocol by a psychiatrist working in the therapy program. The focus of therapy is on the patient's moment-to-moment state of mind. The patient and therapist collaboratively try to generate alternative perspectives to the patient's subjective experience of himself or herself and others by moving from validating and supportive interventions to exploring		treatment and 2.7 yrs of assertive community support, compared with 2 yrs and 5 mths, respectively, for the MBT group. The TAU group had an average of over 3 yrs taking antipsychotic medication, whereas the MBT group had less than 2 mths. Smaller but still substantial differences were apparent in antidepressant and mood stabilizer use. The TAU group spent nearly 2 yrs taking three or more psychoactive medications, compared to an average of 2 mths for the MBT group. At the end of the follow-up period, 13% of the MBT patients met diagnostic criteria for BPD, compared with 87% of the TAU group. The contrast between mean total scores for the Zanarini Rating Scale for BPD yielded a large effect size favouring the MBT group, albeit with a wide confidence interval. Multivariate analysis of variance across the four	2) global functioning as measured by the Global Assessment of Functioning Scale (GAF) at 6-month intervals after 18 months of MBT by partial hospitalization: TX profiles (emergency room visits, hospitalization, psychiatric outpatients, community support, psychotherapy, medication) and suicidality and self-harm using criteria defined in the original trial for each patient by interview and scrutiny of medical records. borderline personality disorder: a randomized controlled trial. Am J Psychiatry 1999; 156:1563–1569)				and integrated program provided by a supervised team. Expressive therapy using art and writing groups is included. Crises are managed within the team; medication is prescribed according to protocol by a psychiatrist working in the therapy program. The focus of therapy is on the patient's moment-to-moment state of mind. The patient and therapist		assertive community support, compared with 2 yrs and 5 months, respectively, for the mentalization-based treatment group. The TAU group had an average of over 3 yrs taking antipsychotic medication, whereas the mentalization-based treatment group had less than 2 months. Smaller but still substantial differences were apparent in antidepressant and mood stabilizer use. The TAU group spent nearly 2 yrs taking three or more psychoactive medications, compared to an average of 2 months for the mentalization-based treatment group. At the end of the follow-up period, 13% of the mentalization-based treatment patients met diagnostic criteria for BPD, compared with 87% of the TAU group. The contrast between mean total scores for the Zanarini Rating Scale for BPD yielded a large effect size favouring the mentalization-based treatment group, albeit with a	Global Assessment of Functioning Scale (GAF) at 6-month intervals after 18 months of mentalization-based treatment by partial hospitalization: TX profiles (emergency room visits, hospitalization, psychiatric outpatients, community support, psychotherapy, medication) and suicidality and self-harm using criteria defined in the original trial for each patient by interview and scrutiny of medical records. Collected data twice yearly on vocational status, calculating the number of 6-month periods in which the patient was		treatment, d= 0.93 (-4, 1.5) No. of yrs further therapy 36 months post-intake, d= 0.07 (-0.23, 0.37) No. of yrs further assertive outreach treatment, d=1.8 (1.4, 2.2) Medication (yrs) antidepressants, d= 1.1 (0.45, 1.7) Medication (yrs) antipsychotics, d= 2.04 (1.6, 2.5) Medication (yrs) mood stabilisers, d=1.17 (0.73, 1.6) Medication (yrs) three or more drugs, d= 1.45 (1.1, 1.8)

Bateman, A., & Fonagy, P. (2009). Randomized controlled trial of outpatient mentalization-based treatment versus structured clinical management for borderline personality disorder. American Journal of Psychiatry, 166(12), 1355-1364. UK	RCT Level II	N=134 MBT (T) n= 71 SCM (C) n= 63 MBT = mentalization-based treatment SCM = structured clinical management	Age mean (SD) TX= 31.3 (7.6) C=30.9 (7.9) Female (n, %) TX= 57, 80.3% C= 50, 79.4% Diagnosis - All participants were assessed using the Structured Clinical Interview for DSM-IV (SCID-I and SCID-II). Ethnicity - White British/Euro pean MBT: 76.1%, SCM: 68.3%; Black African/Afro -Caribbean MBT: 15.5%, 20.6% Other	Mentalization-based treatment (MBT) is manualized, consisting of 18 months of weekly combined individual and group psychotherapy provided by two different therapists. MBT is a psychodynamic treatment rooted in attachment and cognitive theory. It requires limited training with moderate levels of supervision for implementation by	Protocol-driven treatment, structured clinical management (SCM), in an outpatient context representing best current clinical practice. Practitioners received equivalent supervision. Crisis plans were developed collaboratively within each treatment team for all patients. SCM therapists focused on support and problem solving.	Summary: This study suggests that structured, integrated psychological and psychiatric treatment offering coordinated clinical management recommended by NICE significantly benefits patients with borderline personality disorder. Both conditions were associated with substantially reduced suicidality, self-harm, and hospitalization and improvement on measures of symptoms and social and interpersonal functioning by the end of treatment. The rate of improvement in both groups was higher than spontaneous remission of symptoms of BPD. Although patients in both groups made statistically significant improvements, MBT was associated with greater improvements than SCM for most outcomes. Detail: Suicidal behaviour: Six-month periods free of suicidal behaviours, severe self-injurious behaviours, and hospitalization improved from	Primary outcome: proportion of each group without severe parasuicidal behaviour as indicated by 1) suicide attempt, 2) life-threatening self-harm, or 3) hospital admission. Hospital admission was included because patients are primarily offered inpatient care in anticipation of suicide attempts and severe self-harm Secondary outcome: were independently rated Global Assessment of Functioning (GAF) scores at the beginning and end of treatment and self-reported psychiatric symptoms, social and interpersonal functioning, and	18 mths Assessed at entry and over the course of an 18-mth treatment at 6, 12, and 18 mths. 			for psychotic disorder or bipolar I disorder, 3) had opiate dependence requiring specialist treatment, or 4) had mental impairment or evidence of organic brain disorder. Current psychiatric inpatient treatment, temporary residence, drug/alcohol misuse, and comorbid personality disorder were not exclusion criteria.	developed collaboratively within each treatment team for all patients. MBT therapists focused on helping patients reinstate mentalising during a crisis via telephone contact. SCM therapists focused on support and problem solving		with SCM. During the 6 months before end of treatment fewer patients in the MBT group severely self-harmed (24% versus 43%, $\chi^2=4.6$, $p<0.05$; relative risk=0.55, 95% CI=0.33–0.92). However, during the first 6 months of tx, comparison of the proportion of individuals manifesting self-injurious behaviour favoured the SCM group (75% versus 59%, $\chi^2=3.1$, $p<0.08$; relative risk=1.27, 95% CI=0.99–1.63). From 6 to 18 months the proportion of these patients in the MBT group who self-harmed showed a steeper decline when compared with the SCM group. The more consistent reduction in the counts of self-injurious behaviour and the difference in incidence rate ratios favouring MBT was highly statistically significant. Hospitalisation: Before treatment about 25% of each group had had at least one hospital admission. During the first 6 months of treatment patients in the MBT

training for emotional predictability and problem solving for borderline personality disorder. Journal of Nervous and Mental Disease, 198(4), 299-304. The Netherlands			number of participants were assigned to a group, the remaining spots were randomly assigned to subjects who did not meet full BPD criteria (these participants were not included in this analysis). Age mean (SD) Treatment 32.9 (5.6) Control 31.8 (9.2) Gender – female (n, %) Treatment 35, 83.3% Control 33, 89.2%	skills training with general CBT elements and has a strong systems component; family members and significant others are actively involved in the program. The Dutch version of the STEPPS group program involves 18 weekly sessions and a single follow-up session 3 to 6 months after the conclusion of the program.	treatment for BPD offered at the participating sites. This treatment consisted of individual therapy from a psychotherapist, psychologist, or psychiatric nurse, offered every 1 to 4 weeks. STEPPS-related treatments like DBT or family groups for family members of the patients were not allowed. In both conditions, the main treatment could be supplemented with	symptomatology and improved quality of life, also in the longer run. STEPPS was not superior to TAU in reducing impulsive and parasuicidal behaviours, but this may be explained by the low base rate of these behaviours in our sample. It may also be that a more intensive treatment, such as DBT, is required to find differential effects on these behaviours. The merit of the STEPPS program is that it is relatively easily learned and implemented, and nevertheless improves BPD treatment in a number of ways. Further research to compare this treatment with other effective treatments is warranted. Importantly, this RCT on STEPPS is the first done by others than its developers. Detail: Scores on the primary efficacy measures. SCL-90 and BPD-40 symptom scores generally decreased from T1 to T3, and more so in the STEPPS group than in the TAU group. Quality of life scores (WHOQOL-Bref) generally increased from T1 to T3.	40) respectively. Secondary outcome measures included impulsive and parasuicidal behaviour, and quality of life. Impulsive and parasuicidal behaviour were assessed using 2 subscales of the Borderline Personality Disorder Severity Index-IV (BPDSI-IV). The impulsivity subscale contains 11 items reflecting potentially harmful impulsive behaviours (e.g., gambling, reckless driving, binge eating). The parasuicide subscale contains 13 items reflecting self-mutilating Parasuicidal behaviours and suicidal thoughts and attempts. Quality of life was	before the start of the intervention. Post-treatment assessments (T2) were done after the final weekly session of the STEPPS program (mean 23.9 ±3.6 weeks after T1). Follow-up assessments (T3) took place approxi	90, -47.0 (95% CI, -78.2 to -15.9, p = 0.003); BPD-40, -18.7 (95% CI, -31.6 to -5.8, p =0.005). At 6-month follow-up (T3), the differences were smaller but still significant: SCL-90, -38.4 (95% CI, -67.1 to -9.6, p =0.009); BPD-40, -14.7 (95% CI, -26.6 to -2.8, p =0.016). Secondary outcomes: In the domain of Psychological Health, STEPPS scores were higher than TAU scores particularly at T2 (estimated mean difference	completed but yielded similar results to the per-protocol analysis so only the per-protocol analysis was presented. The comparability of treatment between sites and the comparability between different therapists was not assessed. QC 1.1=A 1.2=A 1.3=B 1.4=F 1.5=A 1.6=A

			Diagnosis BPD confirmed by administering the BPD modules from the Dutch versions of the Personality Diagnostic Questionnaire and the Structured Clinical Interview for DSM-IV Axis II Disorders. Participants had to be above threshold on either impulsivity and/or parasuicide subscales of the BPD Severity Index-IV Exclusion	The program has 3 main components : (1) psychoeducation about BPD; (2) emotion management skills training; and (3) behaviour management skills training. STEPPS is system-based in that friends and relatives of the patients are explicitly involved in the program for support and reinforcement of the newly learned skills (the "support group").	(medication) contacts with a psychiatrist, social worker, or other health care professional.	Overall treatment effects were found for Overall Quality of Life and General Health, Physical Health, and Psychological Health. For Social Relationships the overall treatment effect was a trend, for Environment the overall treatment effect was not significant. In both conditions, the number of patients scoring above the cut-off for ratings for the parasuicide and impulsivity subscales of the BPDSI-IV decreased from T1 to T3. There were no significant differences between the conditions (overall treatment effects). Medication was similar between the groups at baseline and remained stable during follow-up assessment. Over the entire study period, patients in the STEPPS group received 15 STEPPS group sessions on average, and had a mean of 8 contacts with their individual therapist. TAU-patients had a mean of 9 individual contacts with their main therapist. In addition to these study treatment	measured with the World Health Organization Quality of Life Assessment-Bref (WHOQOL-Bref)	meanly 6 months after T2 (mean 25.7 ±4.2 weeks after T2). Outcome measures were assessed on all 3 occasions	adjusted for T1 score: 2.08 [95% CI, 0.76 – 3.41, p=0.002]; at T3, this difference was reduced to 0.91 (95% CI, -0.32–2.15, p = 0.146). With respect to Overall Quality of Life and General Health, Physical Health and Social Relationships, STEPPS scores were significantly higher than TAU scores only at T3 (estimated differences 1.80 [95% CI, 0.30 –3.30, p= 0.019]; 1.41 [95% CI, 0.15– 2.66, p = 0.028]; and 1.86 [95% CI,	1.7=B 1.8=28.9% (TX) and 13.2% (C) 1.9= 3 1.10=4 2.1 = (+)

India	SR Level 1	n = 24 included topiramate. n=5 were included in final analysis.	Study participants were required to be aggressive adults. Studies included participants below 18 yrs of age provided that the mean age of participants clearly indicated that the majority of participants were adults. Age range 16-61 yrs, with a mean age of 41 yrs. Studies were	Included studies were required to have at least one arm in which topiramate was used as intervention. BPD diagnosis = 3 studies Depression diagnosis = 1 study Chronic Backache diagnosis = 1 study Study 1 - The study dealt with women aged between 20 and 35 yrs who were more	Placebo	Summary: With a fairly good quality of studies in the analysis, the study came to a conclusion that there is sufficient evidence to suggest that topiramate is significantly effective in stabilizing trait anger but appears to reduce state anger, anger-out anger-in and hostility. The reduction in the scores was highest in borderline personality disorder (BPD) patients as compared to those with low back ache. Trait Anger dropped by -2.93 (-3.49 to -2.37), especially in female BPD patients. Anger- In reduced more or less uniformly across the studies by -1.43 (-1.84 to -1.03). Anger-Out decreased by -2.8 (-3.19 to -2.42). This effect was minimal among the male BPD patients. Anger Control uniformly increased across the four studies by 2.32 (2.00-2.64).	(a) Four STAXI scales - State Anger, Trait Anger, Anger Out, Anger Control - or any equivalent measure of component or global response. The State Anger scale assesses the intensity of anger as an emotional state at a particular time. The Trait Anger scale measures how often angry feelings are experienced over time. The Anger Expression and Anger Control scales assess relatively independent anger-related traits: (i) expression of anger toward other persons or objects in the environment	8 – 10 weeks.	CALCULATED weighted mean difference -3.16 (-3.64 to -2.68) in State Anger. Limited detail to allow for effect size calculation.	Primary search was Medline only, also did additional screening of Cochrane and PubMed The sample size was relatively small and the percentage of males included is less compared to that of females. The study duration was generally only 8-10

Ref, Country	Study Design/ Level of Evidence	N (n)	Participants Age Gender Diagnosis Other	Intervention	Comparison	Outcomes	Measure/s	Length of follow- up	Effect Size	Comments
			conducted among patients who suffered from other types of aggression, including that in BPDs.	susceptible to BPD than men and STAXI was used as the primary outcome measure. Study 2 – This study conducted a directed study for BPD in males wherein the same standards (above) as the previous study in females were applied. There were 22 subjects each in the topiramate and placebo arms. Study 3 – This was a 10-wk study, which enrolled 64		There is sufficient evidence to suggest that topiramate is significantly effective in stabilizing the "trait anger" while reducing the "state anger." "Anger-Out" and "hostility" were significantly reduced. "Anger-In" was the feature that was the least affected, although this was significant. This suggests that topiramate is effective in controlling anger. There was no suggestion of topiramate precipitating psychomorbidity. The studies varied in terms of inclusion criteria such as BPD, depression and even low back ache. There were separate studies for men and women.	(Anger-Out), (ii) holding in or suppressing angry feelings (Anger-In) and (iii) controlling angry feelings by preventing the expression of anger toward other persons or objects in the environment or controlling suppressed angry feelings by calming down or cooling off (Anger Control). Individuals rate themselves on the scales that assess both the intensity of their anger at a particular time and the frequency at which anger is experienced, expressed and controlled. (b) Symptoms: a change in self-reported feelings of anger and impulsiveness, either an increase or decrease in the			weeks, which reduced the incidence of adverse effects and the dropout rate. 			<p>78% met criteria for a mood disorder, 40% met criteria for a substance use disorder, 28% met criteria for an anxiety disorder and 50% met criteria for an eating disorder.</p> <p>Exclusion: current psychiatric treatment, met criteria for lifetime /current schizoprenia, schizoaffective disorder or bipolar 1 or current substance dependence (except nicotine)</p>			<p>was a trend for vocational but not social functioning to improve over time for the group taken as a whole. Knowledge of BPD increased (6% answered 6+ questions at baseline but 78% answered 6+ correctly after)</p>				

Clinical Question 7. Which psychological therapies are most effective? (CBT, mentalisation, behaviour therapy, psychodynamic, CAT, group therapy, family therapy, schema-focused therapy, transference-focused and DBT, miscellaneous)

NICE Guideline summary

There is very little evidence for the efficacy of individual psychological interventions in the treatment of people with BPD because almost all studies are uncontrolled. The RCT evidence showed some weak evidence that Cognitive Analytical Therapy (CAT) (in young people) and STEPPS may help to improve general functioning, and reduce self-harm and suicide. The effect size for self-harm and suicide outcome was not quite statistically significant for CAT, which was compared with a manualised treatment and 'good clinical practice'. Other outcomes from the studies of CAT and STEPPS, and outcomes from RCTs of other therapies (Cognitive behavioural therapy (CBT), schema-focused psychotherapy and individual dynamic psychotherapy), did not show any benefit of treatment. Data from the study of transference-focused psychotherapy were not extractable so effect sizes could not be calculated and the study was excluded from the analysis. It should also be noted that the studies had few outcomes in common making the dataset as a whole hard to evaluate. The non-RCT evidence suggests that individual psychological interventions are acceptable to people with borderline personality disorder. They showed generally positive outcomes (based on authors' conclusions from statistical significance testing rather than calculating effect sizes from extracted data), which need to be tested against control conditions in randomised trials before firm conclusions about the efficacy of these treatments can be drawn.

Updated search

Summary

Interpretation of the updated search for Q7 should be made with caution as many studies were conducted prior to 2008 and more recent studies often test more complex clinical questions, or measure specific outcomes, beyond efficacy or effectiveness. Refer to the meta-analysis for Q6 for greater detail and assistance with interpretation. This question should be considered in conjunction with the NICE guideline summary.

Treatment completion rates are good for most types of treatment. Most treatments showed positive effects but many had mixed results with both the treatment and control groups improving. Psychoanalytic/dynamic therapies showed good outcomes the only recent systematic review of psychological interventions for BPD.

DBT

Ref, Country	Study Design/ Level of Evidence	N (n)	Participants Age Gender Diagnosis Other	Intervention	Comparison	Outcomes	Measure/s	Length of follow-up	Effect Size	Comments
Carter, G.L., Willcox, C.H., Lewin, T.J., Conrad, A.M., & Bendit, N. (2010). Hunter DBT project: Randomized controlled trial of dialectical behaviour therapy in women with borderline personality disorder. The Australian and New Zealand journal of psychiatry, (2), 162-173.	RCT Level II The purpose of the present study was to compare dialectical behaviour therapy (DBT) and the control condition of treatment as usual plus weight list (WL) for DBT (TAU+WL).	N=60 Treatment n= 27 Control n= 33	Age mean (SD): Treatment 24.5 ± 6.12; Control 24.7 ± 6.15 Gender: all female Diagnosis: BPD via clinical interview by a psychiatrist using DSM-IV criteria. To be in the study, needed a history of multiple episodes of deliberate self-harm, at least three self-reported episodes in the preceding 12 months. Exclusion: Exclusion	Modified DBT: team-based approach including individual therapy, group-based skills training, telephone access to an individual therapist and therapist supervision groups following the model of treatment developed by Linehan et al. The main change to the Linehan et al. model was the telephone access to individual therapists. In the present study telephone access was delivered using a group roster	WL + TAU The control condition was a 6-month WL for DBT while receiving TAU (TAU+WL). Subjects, both in the initial DBT group and in the TAU+WL group who came to DBT after 6 months were offered 12 months DBT treatment, although the comparison between groups was restricted to the first 6 months of DBT versus TAU+WL.	Summary: The study found no statistically significant differences between modified DBT and waitlist control/TAU except for some quality of life measures. There were trends towards modified DBT in reductions in hospitalisations, shorter lengths of stay, days in bed. Detail: The present study found reductions in psychiatric hospitalization for both DBT and WL+TAU over time but no significant benefit in favour of DBT for the binary outcome, the mean length of stay for those with an admission at the end-point of the trial. There were no significant differences in proportions for general hospital admission for DSH or for any psychiatric admission. The length of stay overall, or the length of stay for those with either type of admission was not	The primary outcomes (differences in proportions and event rates) of any deliberate self-harm (DSH) event; general hospital admission for DSH and psychiatric admission for any reason; and mean difference in length of stay for any hospitalization. Secondary outcomes were disability and quality of life measures. Specific measures: Composite International Diagnostic Interview modules: anxiety, depression, bipolar disorders, alcohol abuse and dependence, substance abuse and dependence International Personality Disorder Examination Questionnaire	3 and 6 month follow-up	BDQ days in bed, d =-0.66 (-1.25, -0.07) BDQ days out of role, d = -0.43 (-1.01, 0.15) Days in hospital, d = -0.16 (-0.62, 0.30) No. hospital admissions, d = -0.22 (-0.68, 0.24) No. hospital presentations without admission, d= 0.03 (-0.43, 0.49) No. self-harm episodes in previous 3 months, d = -0.18 (-0.64, 0.28) WHOQOL-BREF Environmental domain, d= 0.43 (-0.14, 0.99) WHOQOL-BREF Physical domain, d= 0.69 (0.11, 1.27) WHOQOL-BREF	There are several possible explanations given to as to why DBT was not effective in this study: regression to background (pre-baseline) levels, the Hawthorne effect whereby both groups improved because of the effect of being in a study, the potentially powerful effect of being in a 6 month TAU+WL group for DBT for the control condition, beneficial effects of the TAU condition available in the Hunter region, modifications to standard DBT, the possible

Ref, Country	Study Design/ Level of Evidence	N (n)	Participants Age Gender Diagnosis Other	Intervention	Comparison	Outcomes	Measure/s	Length of follow- up	Effect Size	Comments
			criteria were presence of a disabling organic condition, schizophrenia, bipolar affective disorder, psychotic depression, florid antisocial behaviour, or developmental disability	of DBT individual therapists (not contact with each participant's individual therapist) between 8:30 a.m. and 10 p.m., and telephone contact with the local psychiatric hospital between 10 p.m. and 8:30 a.m. Treatment subjects were also assigned to the relevant skills training group, meeting weekly with the modules running in the following order: Interpersonal Effectiveness, Emotion Regulation and Distress Tolerance.		significantly different, although the DBT group tended to have shorter lengths of stay. For the per-protocol analyses, there were no significant differences for the proportion of patients with any DSH episode in 6 months, or for the number of self-harm episodes for the baseline–3 months and 3–6 months periods. There was a significant benefit in favour of DBT for days spent in bed but no significant effect for days out of role. There was a significant beneficial effect in favour of DBT, for three of the four domains of quality of life: Physical, Psychological and Environmental.	Brief Disability Questionnaire Lifetime Parasuicidal Count-2 Parasuicidal History Interview- 3 month period WHO Quality of Life-BREF version		Psychological domain, $d = 0.65$ (0.07, 1.23) WHOQOL-BREF Social domain, $d = -0.04$ (-0.60, 0.53)	inferiority of training of DBT therapists to that of those in other studies or inferior adherence to the DBT methods despite adequate training, and methodological differences. Very clear on methods of randomisation and concealment (sealed envelopes). Randomization occurred after baseline assessment. Hospitalisation data was intention to treat but rest was per-protocol. Large discrepancy in drop outs between groups.

Rowe S.L, Jordan J, McIntosh V.V, Carter F.A, Bulik C.M, Joyce P.R. (2008) Impact of borderline personality disorder on bulimia nervosa. Aust N Z J Psychiatry. Dec; 42(12), 1021-9. New Zealand	Follow-up of RCT Level II Follow-up of subjects from previous RCT which evaluated the additive efficacy of exposure-based vs. non-exposure-based behavioural treatments to a core of cognitive behaviour therapy for BN.	N=134 Follow-up data for 101 at 1 yr and 112 at 3 yrs	28% (n=38) met DSM-III-R criteria for BPD. Participants: women 17-45 yrs (n=134), with a current DSM-III-R diagnosis of BN. Exclusion criteria were AN, obesity (BMI>30), severe MDD, substance use disorder, BPAD, schizophrenia, a severe medical illness or complications of BN, use psychoactive meds and unwillingness to undergo supervised drug wash-	All participants received eight sessions of cognitive therapy before being randomized to a further eight sessions of one of three forms of behavioural therapy: (i) exposure to pre-binge cues with bingeing being prevented (B-ERP); (ii) exposure to pre-purge cues with purging being prevented (P-ERP); or (iii) relaxation training (RELAX).	All participants received eight sessions of cognitive therapy before being randomized to a further eight sessions of one of three forms of behavioural therapy: (i) exposure to pre-binge cues with bingeing being prevented (B-ERP); (ii) exposure to pre-purge cues with purging being prevented (P-ERP); or (iii) relaxation training (RELAX).	Summary: All three groups improved. Those with bulimia nervosa (BN) did not have worse outcomes compared to those who did not have BN Detail: Women with BN and BPD did not differ significantly from the other PD and no PD groups in eating disorder symptoms and attitudes at 1 year and 3 year follow up. General and psychiatric functioning as measured on the GAF and HDRS showed improvements for all three groups at 1 year follow up. No significant differences among the groups were found at 1 year follow up. At 3 year follow up eating disorder symptoms were improved in all three groups and general psychiatric functioning did not differ among the three groups. Overall, the BPD group had the lowest rate of any eating disorder diagnoses at follow up - 35% and 24% at 1 and 3 yrs, respectively, compared to 45% and 31% for other PD and 38% and 36% for no PD. Differences in personality profiles between the BPD and	Eating disorder symptoms and general functioning- Comprehensive Bulimia Severity Index (CBSI) Depression – HDRS Global Assessment of Functioning – GAF Personality traits - Temperament and character inventory (CTI)	Follow-up data were available for 101 women (75%) at 1 yr follow up and 112 (84%) at 3 yr follow up. Ninety-two participants were available for all three time points (including baseline).	There was a significant effect for HA in the BPD (Wilks' λ =0.34, $F(2,14)$ =13.88, $p<.001$, multivariate partial η^2 = 0.67) and no PD groups (Wilks' λ =0.67, $F(2,34)$ =8.5, $p<.001$, multivariate partial η^2 = 0.33). SD also showed significant within-group effects in the no PD group across 3 yrs (Wilks' λ = 0.51, $F(2,34)$ =16.36, $p<.001$, multivariate partial η^2 = 0.49). Despite an increase of one standard deviation in SD, the BPD group had a smaller effect	Overall, despite having a marginally poorer clinical presentation at pre-treatment assessment, women with BN and comorbid BPD did not have a worse eating disorder or general functioning outcome at 3 yrs after treatment than those with other or no PDs, indicating that in regard to this clinical question, the treatment for BN offered to this sample required no modification for the subjects with BPD. However the small sample size in the 3 groups may have decreased the power to detect significant differences, increasing the

Bateman, A., & Fonagy, P. (2008). 8-year follow-up of patients treated for borderline personality disorder: Mentalization-based treatment versus treatment as usual. American Journal of Psychiatry, 165(5), 631-638. (follow up from Bateman A, Fonagy P. (1999) Effectiveness of partial hospitalization in the treatment of borderline personality	RCT Level II RCT (8 yrs since intervention follow-up – reporting occurrences since the 3 year follow-up).	N=41 T=22 C= 19	Age and gender not reported. Diagnosis: BPD on both Structured Clinical Interview for DSM-III-R and Diagnostic Interview for Borderline Patients. Exclusion: If they met criteria for schizophrenia, bipolar, substance misuse or mental impairment or had evidence of organic brain disorder.	Partial hospitalisation consisting of a long-term psychoanalytically orientated treatment for 18 months. Metallization based treatment (MBT) individual and group therapy. MBT by partial hospitalization consists of 18-month individual and group psychotherapy in a partial hospital setting offered within a structured and integrated program provided by a supervised team. Expressive	Treatment as usual (TAU) consists of general psychiatric outpatient care with medication prescribed by the consultant psychiatrist, community support from mental health nurses, and periods of partial hospital and inpatient treatment as necessary but no specialist psychotherapy.	Summary: Those in MBT showed greater reduction in self harm and suicide, ED visits, treatment attendance. 13% v 87% of TAU still met criteria for BPD at 8 year follow-up. TAU group used more external treatments and greater length of use of medication Detail: 23% made suicide attempts in the MBT group (mean attempts 0.5±0.9), contrasted with 74% of the TAU group (mean attempts 0.52±0.48), which was significant. Mean number of emergency room visits and hospital days highly significantly favoured the MBT group, as did the continuing treatment profile. During MBT group therapy, all of the experimental group but only 31% of the TAU group received therapy. Over the 5-year postdischarge period, both groups received around 6 months of psychological therapy (n.s.). For all other treatments, the TAU group received significantly more input postdischarge—3.6 yrs of psychiatric outpatient treatment and 2.7 yrs of assertive community support, compared	Primary: number of suicide attempts over the whole of the 5 year post-discharge follow-up period. Associated outcomes were service use, including emergency room visits; the length and frequency of hospitalization; continuing outpatient psychiatric care; and use of medication, psychological therapies, and community support. Secondary: 1) symptom status as assessed at a follow-up interview using the Zanerini Rating Scale for DSM-IV borderline personality disorder 2) global functioning as	2 yrs	Suicide attempts total, d =1.4 (0.3, 1.5) Zanerini Rating Scale (ZRS) for BPD: total: d = 1.8 (0.14, 3.5), affect: d=1.1 (0.41, 1.7), cognitive: d = 0.84 (0.3, 1.4), impulsivity: d = 1.2 (0.59, 1.9), interpersonal: d = 1.6 (1, 2.3) GAF, d= 0.75 (-1.9, 3.4) No. of days of hospitalisation, d = 1.5 (0.36, 2.7) No. of emergency room visits, d = 1.4 (0.21, 2.63) No. of yrs of	QC 1.1=A 1.2=B 1.3=B 1.4=B 1.5=B 1.6=A 1.7=A 1.8= 0% and 18% 1.9= C 1.10=F 2.1 = (+)

disorder: a randomized controlled trial. Am J Psychiatry. 156, 1563– 1569.				therapy using art and writing groups is included. Crises are managed within the team; medication is prescribed according to protocol by a psychiatrist working in the therapy program. The focus of therapy is on the patient's moment-to- moment state of mind. The patient and therapist collaboratively try to generate alternative perspectives to the patient's subjective experience of himself or herself and		with 2 yrs and 5 months, respectively, for the MBT group. The TAU group had an average of over 3 yrs taking antipsychotic medication, whereas the mentalization-based treatment group had less than 2 months. Smaller but still substantial differences were apparent in antidepressant and mood stabilizer use. The TAU group spent nearly 2 yrs taking three or more psychoactive medications, compared to an average of 2 months for the MBT group. At the end of the follow-up period, 13% of the MBT patients met diagnostic criteria for BPD, compared with 87% of the TAU group. The contrast between mean total scores for the Zanzarini Rating Scale for BPD yielded a large effect size favouring the MBT group, albeit with a wide confidence interval. Multivariate analysis of variance across the four symptom clusters also reflected the better outcome for the MBT group (Wilks's $\lambda = 0.55$, $F = 6.4$, $df = 4, 32$, $p = 0.001$). The largest differences favouring MBT were in terms of impulsivity	measured by the Global Assessment of Functioning Scale (GAF) at 6- month intervals after 18 months of MBT by partial hospitalization: TX profiles (emergency room visits, hospitalization, psychiatric outpatients, community support, psychotherapy, medication) and suicidality and self- harm using criteria defined in the original trial for each patient by interview and scrutiny of medical records. It requires limited training with moderate levels of supervision for implementation by generic mental health professionals. It aims to strengthen patients' capacity to understand their own and others' mental states in attachment contexts in order to address their difficulties with affect, impulse regulation, and	equivalent supervision. Crisis plans were developed collaboratively within each treatment team for all patients. SCM therapists focused on support and problem solving.	in patients assigned to MBT more than for patients in the SCM group, however, differences only became statistically significant after 12 months of treatment. Number of episodes of hospital admissions, suicide attempts, and severe self-injuries) also declined in both groups but a substantially greater reduction in the MBT than the SCM group. Data were relatively consistent showed reduced suicidal behaviour in both groups. The rate of improvement was significantly greater in the MBT group both in terms of any suicide attempt and the count data associated with it. Differences between groups only became marked in the last 6 months of treatment; at 12 months, groups were not significantly different. Self-harm: Frequency of self-harm behaviours had significantly steeper reduction in the MBT group compared with SCM. During the 6 months before end of treatment fewer patients in the MBT group severely self-harmed (24% versus 43%, $c^2=4.6$, $p<0.05$; relative risk=0.55, 95% CI=0.33–0.92).	care in anticipation of suicide attempts and severe self-harm Secondary outcome: were independently rated Global Assessment of Functioning (GAF) scores at the beginning and end of treatment and self-reported psychiatric symptoms, social and interpersonal functioning, and medication use assessed at baseline and at 6-month intervals until the end of treatment at 18 months. Patients' subjective experience of symptoms was measured using the SCL-90-R, and depression was assessed by using the Beck Depression Inventory.		Social adjustment problems, $d = 0.72$ (0.37, 1.06) Symptom distress, $d = 0.67$ (0.33, 1.02) Depression, $d=0.45$ (0.1, 0.79) Hospital admissions, suicidal and self-injurious episodes, $d=-0.72$ (-1.07, -0.37) Length of hospitalisation, $d=-0.43$, (-0.78, -0.09) Medication use, $d=-0.58$, (-0.93, -0.24) Psychiatric hospitalisation, $d= -0.53$, (-0.88, -0.19)	ded by NICE significantly benefits patients with borderline personality disorder. Both conditions were associated with substantially reduced suicidality, self-harm, and hospitalization and improvement on measures of symptoms and social and interpersonal functioning by the end of treatment. The rate of

Ref, Country	Study Design/ Level of Evidence	N (n)	Participants Age Gender Diagnosis Other	Intervention	Comparison	Outcomes	Measure/s	Length of follow-up	Effect Size	Comments
			3) age 18–65. Exclusion criteria were kept to a minimum. Patients were excluded if they currently 1) were in long-term psychotherapeutic treatment, 2) met DSM-IV criteria for psychotic disorder or bipolar I disorder, 3) had opiate dependence requiring specialist treatment, or 4) had mental impairment or evidence of organic brain disorder.	interpersonal functioning, which act as triggers for acts of suicide and self-harm. Crisis plans were developed collaboratively within each treatment team for all patients. MBT therapists focused on helping patients reinstate mentalising during a crisis via telephone contact. SCM therapists focused on support and problem solving		<p>However, during the first 6 months of tx, comparison of the proportion of individuals manifesting self-injurious behaviour favoured the SCM group (75% versus 59%, $c^2=3.1$, $p<0.08$; relative risk=1.27, 95% CI=0.99–1.63).</p> <p>From 6 to 18 months the proportion of these patients in the MBT group who self-harmed showed a steeper decline when compared with the SCM group. The more consistent reduction in the counts of self-injurious behaviour and the difference in incidence rate ratios favouring MBT was highly statistically significant.</p> <p>Hospitalisation: Before treatment about 25% of each group had had at least one hospital admission. During the first 6 months of treatment patients in the MBT group had significantly fewer days in hospital (Kruskal-Wallis $c^2=4.25$, $p<0.04$), and the difference increased by 12 months (Kruskal-Wallis $c^2=6.54$, $p<0.02$) and 18 months (Kruskal-Wallis $c^2=9.01$, $p<0.003$).</p> <p>The decline in number of admissions over the whole period</p>	Social adjustment and interpersonal functioning were measured using the modified Social Adjustment Scale–self-report and the Inventory of Interpersonal Problems–circumflex version. The instruments provide an assessment of an individual’s work, spare time activities, and family life as well as difficulties with interpersonal functioning.			improvement in both groups was higher than spontaneous remission of symptoms of BPD. Although patients in both groups made statistically significant improvements, MBT was associated with greater improvements than SCM for most outcomes. Very good description of factors similar between groups and randomisation

						<p>1.3), moderate for social adjustment problems ($d=0.72$, 95% CI=0.37–1.06) and symptom distress ($d=0.67$, 95% CI=0.33–1.02), and more modest for depression ($d=0.45$, 95% CI=0.10–0.79).</p> <p>Medication: use of medication reduced significantly in both groups. The proportion of patients not receiving medication increased from 27% to 57%. The increase was greater for the MBT group. Counting the number of classes of psychotropic medication also showed a decline across both groups with the incidence rate ratio suggesting a significant difference in favour of the MBT group. The number of people receiving two or more different classes of medication substantially reduced in both groups from 30% at the beginning of treatment to 8% at the end of treatment.</p>				

STEPPS

Ref, Country	Study Design/ Level of Evidence	N (n)	Participants Age Gender Diagnosis Other	Intervention	Comparison	Outcomes	Measure/s	Length of follow-up	Effect Size	Comments
Bos, E.H., Van Wel, E.B., Appelo, M.T., & Verbraak, M.J. (2010). A randomized controlled trial of a Dutch version of systems training for emotional predictability and problem solving for borderline personality disorder. Journal of Nervous and Mental Disease, 198(4), 299-304. The Netherlands	RCT Level II Randomization was done separately at each location.	N=79 TX (n = 42) C (n = 37)	Between 8 and 12 subjects were included in each group for the Treatment group. If at the time of randomisation, an insufficient number of participants were assigned to a group, the remaining spots were randomly assigned to subjects who did not meet full BPD criteria (these participants were not included in this analysis).	Systems Training for Emotional Predictability and Problem Solving (STEPPS) + individual treatment Group treatment; it combines skills training with general CBT elements and has a strong systems component; family members and significant others are actively involved in the program. The Dutch version of the STEPPS group program involves 18 weekly sessions and a single follow-up session 3 to 6 months after the conclusion of the program. The program has 3 main components: (1)	Treatment as usual (TAU): The STEPPS groups began simultaneously with a group of patients that started TAU. The control condition was TAU, i.e., the standard treatment for BPD offered at the participating sites. This treatment consisted of individual therapy from a psychotherapist, psychologist, or psychiatric nurse, offered every 1 to 4 weeks. STEPPS-related treatments like DBT or	Summary: Both groups improved on measures of BPD pathology and general functioning, QoL, medication use and treatment attendance but STEPPS showed greater improvement than TAU. No differences in parasuicide measures Detail: Scores on the primary efficacy measures. SCL-90 and BPD-40 symptom scores generally decreased from T1 to T3, and more so in the STEPPS group than in the TAU group. Quality of life scores (WHOQOL-Bref) generally increased from T1 to T3. Overall treatment effects were found for Overall Quality of Life and General Health, Physical Health, and Psychological Health. For Social Relationships the overall treatment effect was a trend, for Environment the overall treatment effect was not	Primary efficacy measures included general psychiatric and BPD-specific symptoms, measured with the Symptom Checklist-90 total score (SCL-90) and the Borderline Personality Disorder checklist-40 total score (BPD-40) respectively. Secondary outcome measures included impulsive and parasuicidal behaviour, and quality of life. Impulsive and parasuicidal behaviour were assessed using 2 subscales of the Borderline Personality	Pre-treatment assessments (T1) took place following randomization, just before the start of the intervention. Post-treatment assessments (T2) were done after the final weekly session of the STEPPS program (mean 23.9 ±3.6 weeks after T1). Follow-up assessments (T3) took place	Effect sizes (non-standardised): Primary outcomes: Estimated mean differences at the end of treatment (T2), adjusted for differences at T1, were: SCL-90, -47.0 (95% CI, -78.2 to -15.9, p = 0.003); BPD-40, -18.7 (95% CI, -31.6 to -5.8, p = 0.005). At 6-month follow-up (T3), the differences were smaller but still significant: SCL-90, -38.4 (95% CI, -67.1 to -9.6, p =0.009); BPD-40, -14.7 (95% CI, -26.6 to -2.8, p =0.016). Secondary outcomes: In the domain of Psychological	Moderate to large effect sizes were seen for symptom variables and psychological quality of life at T2. At T3, moderate effects on symptoms were still present, while also moderate effects on physical, social and overall quality of life could be observed. More than TAU, STEPPS plus limited adjunctive individual therapy reduced symptomatology and improved quality of life, in the longer run. STEPPS was not

			<p>Age mean (SD) Treatment 32.9 (5.6) Control 31.8 (9.2)</p> <p>Gender – female (n,%) Treatment 35, 83.3% Control 33, 89.2%</p> <p>Diagnosis: BPD confirmed by administering the BPD modules from the Dutch versions of the Personality Diagnostic Questionnaire and the Structured Clinical Interview for DSM-IV Axis II Disorders. Participants</p>	<p>psychoeducation about BPD; (2) emotion management skills training; and (3) behaviour management skills training. STEPPS is system-based in that friends and relatives of the patients are explicitly involved in the program for support and reinforcement of the newly learned skills (the “support group”). They receive education about BPD and are instructed how to interact with the person with the disorder. STEPPS is administered by 2 mental health professionals, of who at least one is a psychotherapist. Subjects assigned</p>	<p>family groups for family members of the patients were not allowed. In both conditions, the main treatment could be supplemented with (medication) contacts with a psychiatrist, social worker, or other health care professional.</p>	<p>significant. In both conditions, the number of patients scoring above the cut-off for ratings for the parasuicide and impulsivity subscales of the BPDSI-IV decreased from T1 to T3. There were no significant differences between the conditions (overall treatment effects). Medication was similar between the groups at baseline and remained stable during follow-up assessment. Over the entire study period, patients in the STEPPS group received 15 STEPPS group sessions on average, and had a mean of 8 contacts with their individual therapist. TAU-patients had a mean of 9 individual contacts with their main therapist. In addition to these study treatment contacts, TAU-patients reported to have had 31 ambulatory therapy contacts on average with other mental health care</p>	<p>Disorder Severity Index-IV (BPDSI-IV). The impulsivity subscale contains 11 items reflecting potentially harmful impulsive behaviours (e.g., gambling, reckless driving, binge eating). The parasuicide subscale contains 13 items reflecting self-mutilating parasuicidal behaviours and suicidal thoughts and attempts. Quality of life was measured with the World Health Organization Quality of Life Assessment-Bref (WHOQOL-Bref)</p>	<p>approximately 6 months after T2 (mean 25.7 ±4.2 weeks after T2). Outcome measures were assessed on all 3 occasions</p>	<p>Health, STEPPS scores were higher than TAU scores particularly at T2 (estimated mean difference adjusted for T1 score: 2.08 [95% CI, 0.76 –3.41, p = 0.002]); at T3, this difference was reduced to 0.91 (95% CI, -0.32 – 2.15, p = 0.146). With respect to Overall Quality of Life and General Health, Physical Health and Social Relationships, STEPPS scores were significantly higher than TAU scores only at T3 (estimated differences 1.80 [95% CI, 0.30 – 3.30, p = 0.019]; 1.41 [95% CI, 0.15 – 2.66, p = 0.028]; and 1.86</p>	<p>superior to TAU in reducing impulsive and parasuicidal behaviours, but this may be explained by the low base rate of these behaviours in our sample. It may also be that a more intensive treatment, such as DBT, is required to find differential effects on these behaviours. The merit of the STEPPS program is that it is relatively easily learned and implemented, and nevertheless improves BPD treatment in a number of ways. Further</p>

Bellino, S., Zizza, M., Camilla, R., & Filippo, B. (2006) Combined treatment of major depression in patients with borderline personality disorder: A comparison with pharmacother- apy. Canadian Journal of Psychiatry, 51(7), 453- 460. Italy	RCT Level II	N=39 enrolled N=32 analysed	39 participants with DSM-IV-TR diagnosis of BPD who met clinical and DSM-IV criteria for a major depressive episode (mild to moderate). Mean age of 26.4 yrs (SD 3.7); male to female ratio 3:5. Subjects were selected from patients attending the Service for Personality Disorder of the Unit of Psychiatry, Department of Neuroscience, University of Turin. Excluded were those with a lifetime diagnosis of delirium, dementia,	20 patients received fluoxetine (see control group for schedule) plus IPT. IPT consisted of weekly, manualised sessions lasting 1 hour. Patients in the combined therapy group were treated by a psychotherapi- st who was not the psychiatrist prescribing the medication and who had 5 yrs of experience practicing IPT. The psychotherap- y and the pharmacother- apy started at the same time.	19 patients received fluoxetine 20 mg to 40 mg daily plus clinical management. Initially, fluoxetine was prescribed at a fixed dosage of 20 mg daily with the opportunity to increase the dosage to 40 mg daily beginning in Week 2, depending on clinical judgment.	Summary: Small sample size does not allow strong conclusions to be drawn from this study but results suggest that combined therapy for BPD patients with comorbid depression may be superior to fluoxetine alone in improving symptoms of depression and social and psychological functioning Detail: Of 39 subjects, 7 dropped out (4 in medication- only, 3 in combined therapy). Only subjects that completed the study were included in the analysis (n=32). Changes in depression remission rates, CGI, and HARS score did not differ between treatments with 75% (n =12) of combined-treatment patients and 62.5% (n =10) of medication-only patients achieving remission ($\chi^2 = 0.562$, $p = 0.446$). (Remission was defined by a decreased HDRS score ($\geq 40\%$), with a final score of ≤ 8 , and a score of 1 (very much improved) or 2, (much improved) on the Improvement item of the CGI). Using a univariate General Linear Model to calculate the effects of 1) duration of	Depression (Hamilton Depression Rating Scale - HDRS) Anxiety (Hamilton Anxiety Rating Scale - HARS) Quality of life (SAT-P satisfaction profile) Self- assessed interpersona- l functioning (64-item Inventory of Interpersona- l Problems) Global functioning (Clinical Global impression Scale - CGI)	Treatment lasted 24 weeks. Assessmen- t at baseline, Week 12, and Week 24.		Participants very poorly described – limited demographic details reported. No description of randomisatio- n procedure. No Intention to treat analysis – only analysed data for completers (i.e. 32 of 39 enrolled) and potential attrition bias due to lack of compliance was not addressed. . 			amnesic or other cognitive disorders, schizophrenia or other psychotic disorders, and patients whose major depressive episode was an expression of bipolar disorder.	Treatment lasted 24 weeks.		<p>treatment and 2) the type of treatment on each assessment scale score, treatment type had a significant effect on HDRS scores - subjects receiving combined therapy had lower mean HDRS scores (T0 mean 18.6, T1 mean 13.6, T2 mean 9.1) than medication only subjects (T0 mean 19.6, T1 mean 15.9, T2 mean 12; $p=0.005$). Duration of treatment also had a significant effect on HDRS scores ($p=0.0005$), but the interaction between the two was not significant.</p> <p>Combined therapy ($p=0.020$) and the interaction of duration and treatment ($p=0.005$) both had significant effects on social functioning and the difference between treatments increased over time.</p> <p>The interaction between combined therapy and treatment duration was superior to medication-only in improving psychological functioning (relates to self-esteem, problem solving, autonomy) as measured by the AST-P (combined T1 mean 47.0, T2 mean 69.0; medication only T1 50.0, T2 57.2; $p=0.017$).</p>				<p>1.7=B 1.8= 15% 1.9=D 1.10=F 2.1 = (+)</p>

Transference focused psychotherapy

Ref, Country	Study Design/ Level of Evidence	N (n)	Participants Age Gender Diagnosis Other	Intervention	Comparison	Outcomes	Measure/s	Length of follow-up	Effect Size	Comments
Doering, S., Horz, S., Rentrop, M., Fischer-Kern, M., Schuster, P., Benecke, C., Buchheim, A., Martius, P., Buchheim, P. (2010). Transference-focused psychotherapy v. Treatment by community psychotherapists for borderline personality disorder: Randomised controlled trial. British Journal of Psychiatry, 196(5), 389-395. Germany	RCT Level II	Treatment n = 52 Control n = 52	Age mean (SD): Treatment 27.46 ±6.8; Control 27.19 ± 7.5 Gender – all females Diagnosis: DSM-IV BPD via Structured Clinical Interview for DSM and Structured Interview for Personality Organisation Exclusion: Exclusion criteria were diagnosis of antisocial personality disorder, schizophrenia, bipolar I and II	Transference-focused psychotherapy (TFP): Two 50-minute sessions are delivered per week. Before treatment starts, a treatment contract is negotiated orally with the individual, covering general aspects like duration and payment as well as potential threats to the treatment specific to each patient (e.g. suicide attempts, drug misuse or anorectic behaviour). The treatment	Treatment by community psychotherapist	Summary: TFP resulted in reduced BPD symptoms compared to Treatment by community psychotherapist. Higher drop out in the control group. No other differences Detail: The drop-out rate was significantly higher in the experienced community psychotherapists group. There were no significant differences between the groups with regard to medication at baseline and during the 1-year treatment period. The TFP group showed a significantly higher proportion of participants that fulfilled less than five DSM-IV diagnostic borderline criteria after 1 year and were not diagnosed BPD any more (42.3% v. 15.4%, P= 0.002). The TFP group was	Primary: Drop-outs Suicide attempts and self-harming behaviour: Cornell Interview for Suicidal and Self-Harming Behaviour-Self Report (CISSB), adapted from the Parasuicidal History Interview Secondary: DSM-IV diagnostic criteria for BPD via SCID GAF Beck Depression Inventory State-Trait	Follow-up: 1 year	Any suicide attempts during psychotherapy, d = -0.08 (-0.47, 0.30) BDI, d = 0.12 (-0.26, 0.51) Brief symptom inventory, d = 0.08 (-0.31, 0.46) GAF, d = 0.34 (-0.04, 0.73) Level of personality organisation, d = -0.26 (-0.65, 0.12) No. of days in psychiatric inpatient during psychotherapy, d = -0.23 (-0.61, 0.16) No. of DSM-IV diagnostic criteria for BPD, d = -0.56 (-0.95, -0.17) No. of	The results demonstrate the significant superiority of transference-focused psychotherapy with regard to the primary outcome criteria of drop-out rate and suicide attempts during the treatment year. The same was true for the secondary outcome criteria, reduction of DSM-IV diagnostic borderline criteria, psychosocial functioning, level of personality organisation and psychiatric in-patient admissions. Participants in the transference-focused psychotherapy group received 48.5 (s.d. = 34.2) sessions and those in the experienced community psychotherapists group 18.6 (s.d. = 24.0) sessions of individual psychotherapy within the 1-year study period. Future research should look at long-term follow-

Psychoeducation

Ref, Country	Study Design/ Level of Evidence	N (n)	Participants Age Gender Diagnosis Other	Intervention	Comparison	Outcomes	Measure/s	Length of follow- up	Effect Size	Comments
Zanarini, M.C., & Frankenburg, .R. (2008). A preliminary, randomized trial of psychoeducat ion for women with borderline personality disorder. Journal of Personality Disorders, 22(3), 284- 290 USA	RCT Level II	N= 50 Treatment n = 30 Control n = 20	Age mean (SD) in total sample 19.3 ± 1.4 Gender – all female Diagnosis - BPD diagnosed with Diagnostic Interview for DSM-IV Personality Disorders and Revised Diagnostic Interview for Borderlines. These participants were being diagnosed for the first time. Additionally in terms of lifetime disorders, 78% met criteria for a mood disorder, 40% met criteria for a substance use disorder, 28% met criteria for an anxiety disorder and 50% met criteria for an eating disorder. Exclusion: current psychiatric treatment, met criteria for lifetime/current schizophrenia, schizoaffective disorder or bipolar 1 or current substance dependence (except nicotine)	Psychoeduca tion on BPD aetiology, phenomenol ogy, co- occurring disorders, treatment options and longitudinal course	Waitlist (took part in workshop at the end of the 12 week study)	No significant difference in BPD symptoms on ZAN-BPD between groups over time. The mean scores of the groups as a whole declined significantly over time. Declines in interpersonal storminess and general impulsivity (not counting self- mutualisation or suicide) were found to be significantly greater among those in the immediate treatment group than the waitlist. There was no significant difference in SDS impairment ratings between groups. In vocational or social functioning over time. There was a trend for vocational but not social functioning to improve over time for the group taken as a whole. Knowledge of BPD increased (6% answered 6+ questions at baseline but 78% answered 6+ correctly after). Immediate psychoeducation after diagnosis can lead to reductions in interpersonal storminess and general impulsivity. This may be because increased knowledge may be more useful in helping people control behaviour rather than affects or cognition.	Structured Clinical Interview for DSM-IV Axis I disorders Zanarini Rating Scale for DSM-IV BPD (ZAN- BPD) Sheehan Disability Scale (SDS) Knowledge of aspects of BPD	12 weeks	Between group standardised mean differences, d (95% CI): Two forms of impulsivity, d = -0.40 (-0.97, 0.174) Stormy relationships , d = -0.381 (-0.952, 0.190) Other details not reported to calculate effect sizes	QC 1.1=B 1.2=B 1.3=C 1.4=F 1.5=A 1.6=A 1.7=A 1.8=no drop out 1.9= A 1.10=F 2.1 = (+)

Clinical Question 8. Which psychosocial therapies are most effective?

Clinical question 8 was combined with clinical question 7.

Note evidence table under Question 7 should include Question 8 as the Committee determined to merge questions 7 and 8 into a single question:

*Which **psychological or psychosocial** therapies are most effective?*

Clinical Question 9. Which pharmacological therapies maximise benefits while minimising harms? (+ comorbidities)

NICE Guideline summary

The NICE guideline refers to pharmacotherapies on page 211.

Although there were 28 evaluable studies of pharmacological treatments in people with a diagnosis of borderline personality disorder (six of which did not meet inclusion criteria), there were few studies of each individual drug, which makes it difficult to draw firm conclusions. There were no trials of benzodiazepines or of ECT. Also, there were variations in the populations in each study, including inpatients, outpatients and symptomatic volunteers, and those with and without comorbid axis I disorders. This means that there were very few studies for each drug within each setting, and consequently, any calculations have low power. Another problem with this dataset is the large number of outcomes reported by each individual study and the lack of standard outcome rating scales within the research field. This also makes the dataset very hard to analyse. However, a relatively large proportion of the available studies have been published relatively recently, which points to a growing interest in research in this area. This is encouraging for the future. There was some evidence that pharmacological treatments can help to reduce specific symptoms experienced by people with borderline personality disorder including anger, anxiety, depression symptoms, hostility and impulsivity, although this is largely based on single studies. However, there is no evidence that they alter the fundamental nature of the disorder in either the short or longer term. The evidence is weak, and it is far from clear if the effects found are the consequence of treating comorbid disorders. In addition, no drug has UK marketing authorisation for these indications in people with borderline personality disorder. There were too few data to assess quality of life outcomes, self-harm/suicidality (except for omega-3 fatty acids) and service use. It was also not possible to explore potential moderators including:

- % population with bipolar diagnoses
- % psychotic or schizotypal
- high dropout rates.

There were few meaningful data regarding harm, so this was difficult to assess. However, it is well known that treatment with olanzapine can lead to weight gain and diabetes and the use of antipsychotics is associated with significant, and in some cases irreversible, long-term harm, such as tardive dyskinesia. There were no data to suggest that any drug was effective as an overall mood stabiliser in people with borderline personality disorder. There is therefore insufficient evidence for the treatment of borderline personality disorder or of the individual symptoms of borderline personality disorder. However, pharmacological treatments may be appropriate for the treatment of comorbid disorders, such as depression.

The NICE guidelines made several clinical recommendations on the role of drug treatment:

- Drug treatment should not be used specifically for borderline personality disorder or for the individual symptoms or behaviour associated with the disorder (for example, repeated self-harm, marked emotional instability, risk-taking behaviour and transient psychotic symptoms).
- Antipsychotic drugs should not be used for the medium- and long-term treatment of borderline personality disorder.
- Drug treatment may be considered in the overall treatment of comorbid conditions (see Section 8.5.13).
- Review the treatment of people with borderline personality disorder who do not have a diagnosed comorbid mental or physical illness and who are currently being prescribed drugs, with the aim of reducing and stopping unnecessary drug treatment.

Summary

There are now a number of systematic reviews of pharmacological interventions for BPD. Most SRs were well conducted and reported but all reviewed small numbers of studies in each category and most of the included studies had small sample sizes. The heterogeneity of outcomes measured made pooling data difficult. Many studies have found positive effects of pharmacotherapy on a range of symptoms including global symptoms/psychopathology and pharmacotherapies appear to be effective for some co-occurring problems. There was stronger evidence for the effectiveness of mood stabilisers than other pharmacotherapies. Antipsychotics showed some effects, as did some anticonvulsants, but there was little evidence for effectiveness of antidepressants. However, caution is required interpreting these results because of the paucity and heterogeneity of the studies. There have been a number of RCT studies, many with small samples, that have been conducted since the reviews; similar results were found.

Summary table (Systematic reviews)

Reference	Quality/comments	Antidepressants	Mood stabilisers	Antipsychotics	Anticonvulsants	Other
Bellino 2008	- This was a poor quality study – search strategy and methodology not clearly outlined and did not assess quality of included studies. Number of included studies for each drug was small.	MAOIs - may help with atypical depression, anger and impulsivity independent of antidepressant effects Tricyclics - modest effect and high potential for harm SSRIs - may help with affective instability and emotional dyscontrol	Lithium - some effect on core pathology but can be toxic and potentially fatal in overdose Carbamazepine - Some effect on wide range of symptoms including impulsive aggressive behaviour and effective dysregulation Lamotrigine ⁷ - highly significant improvement in anger was observed after 8 weeks of one trial	Tiotixene, Trifluoperazine, Haloperidol, Olanzapine, Aripiprazole showed some effects on a range of symptoms: global symptoms, depression, anxiety, paranoid ideation, psychotic symptoms, obsessive symptoms, rejection sensitivity, suicidal attempts, impulsive aggression, chronic dysphoria Risperidone – no effect	NA	NA

⁷ Lamotrigine and topiramate are anticonvulsants but also used as a mood stabiliser. They are reported under the category reported by the authors of the studies

Reference	Quality/comments	Antidepressants	Mood stabilisers	Antipsychotics	Anticonvulsants	Other
Duggan 2008	++	NA	NA	Reduction in cognitive perceptual and mental state disturbance	Reduction in aggression	NA
Ingenhoven 2010	++	No evidence for effect on impulse control, depressed mood, global functioning. Small effect on anxiety and anger Use is not supported nor is the combined use with antipsychotics	Very large effect on impulsive behavioural dyscontrol, anger, anxiety. Moderate effect on depressed mood. More pronounced effect than antipsychotics on global functioning	Atypicals do not outperform classic neuroleptics	NA	NA
Lieb 2010	+	Little evidence for effectiveness	Effects for valproate, lamotrigine and topiramate but not carbamazepine	Haloperidol reduced anger, flupenthixol reduced suicidal behaviour, aripiprizole reduced pathology	NA	Omega 3 fatty acids may reduce depressive symptoms but few studies
Mercer 2009	+	Moderately effective for short term reduction of depression	Highly effective for anger, moderately effective for depressed mood	Moderate effect on anger, depression. Some evidence that haloperidol may worsen depression	NA	NA
Stoffers 2010	++	Little evidence for effectiveness. May help for comorbidity	NA	Olanzapine may increase self harming, weight gain	NA	NA
Varghese 2010	++	NA	NA	NA	NA	Topiramate resulted in reduction in state anger, anger out, hostility, anger in but not trait anger

Summary table (Randomised trials)

Reference	Quality/ comments	Antidepressants	Mood stabilisers	Antipsychotics	Anticonvulsants	Other
Leiberich 2008	+				<p>Lamotrigine - significant reduction in anger and aggression measured by the STAXI than placebo</p> <p>No serious side effects but some adverse events during the trial: self-mutilation (LG), attempted suicide (placebo) and weight loss (both)</p>	
Loew 2008	+				<p>Topiramate - reduction in aggressive behaviour, anxiety and phobias, obsessiveness, depression, paranoia, interpersonal problems, pain.</p> <p>Improved health and activity related measures, and affective instability.</p> <p>No effect on psychoticism. Mild-moderate side-effects usually with initiating or increasing dose.</p>	
Shafiti 2010	+			Both olanzapine and haloperidol improved but no difference between them – no placebo control group		
Ziegenhorn 2009	-					Significant improvement in hyperarousal for patients with PTSD for clonidine compared to control but not measures of general psychopathology or BPD symptoms. Mild adverse effects reported

						antidepressants on global functioning is negligible. The review suggests that atypical antipsychotics do not outperform the classic neuroleptics. With respect to impulsive-behavioural dyscontrol, the prevalent use of antidepressants (SSRIs) is not validated by this meta-analysis, nor is the second step of adding a traditional antipsychotic drug. Modern mood stabilizers seem to deserve a more prominent position. Prescribing

						0.014) improved in the whole sample. Authors conclude that clonidine might be a useful adjunct to pharmacother apy in patients with BPD who have marked hyperarousal and/or sleep problems and, in particular, in patients with BPD who have a PTSD comorbidity.				

Clinical Question 10. *Among people with BPD, are multimodal therapies (pharmacological, psychological, team approaches, day programs, inpatient programs, family/systems therapies, therapeutic communities) more effective than single modal therapies in reducing suicide/self-harm, psychopathology and increasing functioning?*

NICE guideline summary

NICE refers to combination therapies on page 144.

There are few studies comparing the effects of adding a drug to a psychological therapy on symptoms of borderline personality disorder. Consequently the evidence for an effect is weak. There was no evidence of an effect on symptoms of adding fluoxetine or olanzapine to DBT. However, adding IPT to fluoxetine showed some efficacy (compared with fluoxetine alone) in reducing depression symptoms (clinician-rated measure only), and psychological and social functioning aspects of the quality-of-life measure used (self-rated measures). However, the number of participants in this latter trial is very low (n = 25) and therefore further research is needed to replicate this finding. In the trial comparing IPT with CT, the effect of treatment on outcomes was inconclusive, other than for social functioning where CT improved scores more than IPT. However, this trial is also very small. The evidence does not support any recommendations specifically about the combined use of psychotropic medication and a psychological therapy in the treatment of borderline personality disorder.

Updated search

Summary

There were four new multimodal studies that met the inclusion criteria. Generally studies showed a benefit for combined medication and psychological therapies over medication alone.

Clinical Question 11. *Among people with BPD and comorbidities (medical [HIV/AIDS, diabetes, chronic pain, obesity, chronic fatigue], other personality disorders, other mental health, alcohol and drug disorders, eating disorders, intellectual disability), what treatments are effective in reducing suicide/self-harm, psychopathology and increasing functioning ?*

Please note that Clinical Questions 11 and 13 were combined after searching.

A summary for both questions is provided under Clinical Question 13.

Clinical Question 12. How should complex and severe BPD be managed, including management strategies (over a period of time) and multiple comorbidities?

NICE Guideline summary

NICE did not address this question separately in searches nor specifically in recommendations. They refer to NICE Clinical Guideline 16 on Self Harm for management of self-harm and attempted suicide.

Updated search

The committee chose not to pursue this question further but to refer to the NICE Clinical Guideline 16. A systematic literature review was not undertaken for this question.

Clinical Question 13. How should the treatment of common comorbidities (depression, psychosis, anxiety disorders, bipolar disorder, substance use disorder, other axis II disorders) be altered in the presence of BPD?

Please note that Clinical Question 11 was combined with Clinical Question 13 after searching the literature. A summary for both questions is provided below.

NICE Guideline summary

Notes: NICE did not specifically address this question in searches but made recommendations based on their general searches. NICE does not specifically refer to evidence on studies of comorbidity but refers to a clinical pathway on page 333 of the NICE Guideline.

Comorbidity of major psychiatric disorders in borderline personality disorder is widely reported in the literature, with mood disorders, anxiety disorders, eating disorders and drug and alcohol dependence being particularly common. This may lead to problems in diagnosis as some of the features of these disorders are inextricably linked to those of personality disorder. In general terms, psychiatric symptoms show particular characteristics when they are linked to borderline personality disorder compared with how they are expressed in independent psychiatric disorders. They tend to be short-lived and can fluctuate rapidly, they are likely to occur primarily in the context of interpersonal stress and they respond swiftly to structured interventions, such as admission or other environmental modification. The diagnosis of both borderline personality disorder and a comorbid disorder should therefore be reviewed before treatment is initiated, particularly if any diagnosis was made during an emergency presentation.

Any psychiatric symptoms that are integral to borderline personality disorder should be treated as part of that disorder. However, if a comorbid disorder is present, clinicians should assess the severity of it and follow the appropriate treatment guidelines. Patients with comorbid axis I and axis II disorders should receive best treatment for both disorders. The treating clinician may need to consider referral to another clinician or service for appropriate treatment of the comorbid disorder depending on their own training and experience, the context of treatment for borderline personality disorder and the severity and type of the comorbid disorder. For example, people with borderline personality disorder that is comorbid with a major psychosis, a severe eating disorder or substance dependence on Class A drugs are likely to require additional expertise if they are to have the best chance of improvement. Under these circumstances clinicians are advised to ensure appropriate arrangements are made for co-ordinated care with agreement on responsibilities and roles. If a comorbid disorder is diagnosed in the initial assessment of a person with borderline personality disorder, it may be most appropriate to refer them for treatment for the axis I disorder before commencing treatment for borderline personality disorder. However, if a person is already engaged in treatment for borderline personality disorder and a comorbid axis I disorder develops or becomes apparent during the course of treatment, a care co-ordinator should keep in contact with the person while they are receiving treatment for the axis I disorder so that they can continue with treatment for borderline personality disorder when appropriate.

The situation is more complex if the comorbid disorder includes predominant depression, PTSD or anxiety symptoms. In many patients these problems are best treated within a psychotherapeutic treatment programme for borderline personality disorder itself and no additional psychotherapy offered. If medication is required, integrating prescribing within the treatment programme may prevent inappropriate prescription of drugs.

NICE clinical practice recommendations

- Before starting treatment for a comorbid condition in people with borderline personality disorder, review:
 - the diagnosis of borderline personality disorder and that of the comorbid condition, especially if either diagnosis has been made during a crisis or emergency presentation
 - the effectiveness and tolerability of previous and current treatments; discontinue ineffective treatments.
- Treat comorbid depression, post-traumatic stress disorder or anxiety within a well-structured treatment programme for borderline personality disorder.
- Refer people with borderline personality disorder who also have major psychosis, dependence on alcohol or Class A drugs, or a severe eating disorder to an appropriate service. The care coordinator should keep in contact with people being treated for the comorbid condition so that they can continue with treatment for borderline personality disorder when appropriate.
- When treating a comorbid condition in people with borderline personality disorder, follow the NICE clinical guideline for the comorbid condition.

Updated search

Summary

There were few studies specifically looking at treatment of common comorbidities among people with BPD. Three papers by the same group, which seem to be from the same study, showed dynamic deconstructive psychotherapy was more effective than TAU in addressing both BPD and alcohol use disorder symptoms. One study of Dual focused schema therapy for co-occurring BPD and substance use disorders failed to show any benefit over individual drug counselling (IDC), and in fact IDC appeared to show more sustained reductions in symptoms. One study of Axis I disorders among those with BPD showed an improvement in substance use abstinence with DBT. Studies of anxiety and depression showed few benefits of psychological therapies, including a brief intervention to prevent crises (Cape Cod model). Clonidine showed an improvement in hyperarousal but not BPD symptoms among people with BPD and PTSD. A single study of cognitive therapy for people with BPD and bulimia nervosa concluded that no modification of the usual therapy for BPD was required for this group.

Clinical Question 23. Do families (including children) and families/carers of people with BPD have specific care needs?

NICE Guideline summary

No systematic search was undertaken for this question based on the advice of the GDG. A narrative review is presented in the guidelines. A summary is presented here, but please note NICE did not undertake a systematic search. See page 93 NICE guidelines.

Hoffman et al, 2005 – no evidence that 44 participants (from 34 families) of people with BPD experience surplus stigma. Significant burden assessed by Burden Assessment Scale on Families.

Hoffman et al, 2007 – replicated the 2005 study with 55 participants.

Schiers & Bok, 2007 – administered SCL-90 to 64 individuals related and unrelated to BPD. Both had higher SCL-90 scores than the general population but did not differ from each other.

Updated search

No further papers that met the inclusion criteria were identified in an updated search.

Clinical Question 24. If so, what specific interventions should be offered?

NICE Guideline summary

No additional search was undertaken beyond the initial for this question based on the advice of the GDG. A narrative review is presented in the guidelines. As summary is presented here, but please note this was not a systematic search. See page 94 and 95 NICE guidelines.

- Dixon et al 2001 - showed that families of people with Schizophrenia find psychoeducation and information most helpful.
- Hoffman et al, 2003 - assessed 32 families for knowledge of BPD. Higher knowledge related to higher burden, depression, distress and hostility towards person with BPD.
- Hoffman et al 2005 – impact of Family Connections program 12 week program influenced by DBT on 44 individuals (34 families). Assessment pre, post and 6 month follow-up showed reductions in grief and burden, and enhanced mastery, maintained at follow-up.
- Hoffman et al 2007b – replicated the above with 3 month post assessment.

Updated search

No further papers that met the inclusion criteria were identified in an updated search.

Clinical Question 25. Do family or carers, through their behaviour, styles of relating and relationships, influence clinical and social outcomes or well-being for people with BPD?

NICE Guideline summary

No systematic search was undertaken for this question based on the advice of the GDG. A narrative review is presented in the guidelines. A summary is presented here, but please note NICE did not undertake a systematic search. See page 95 NICE guidelines.

Gunderson et al 2006 – present relationships predict outcomes at 2 years – NICE urges caution in interpretation based on measures used.

Hooley & Hoffman 1999 – followed a group of 35 people with BPD post discharge, assessed expressed emotion with the Camberwell Family Interview and found no association between hostility and criticism and readmission rates and there were fewer admissions in families with higher expressed over-involvement.

Updated search

No further papers that met the inclusion criteria were identified in an updated search.

Clinical Question 26. If so, what interventions should be offered?

NICE Guideline summary

There were no empirical studies to review in this section. See page 96 NICE guidelines.

Updated search (systematic)

No further papers that met the inclusion criteria were identified in an updated search

Additional Question: Research on BPD related to Aboriginal and Torres Strait Islanders

NICE Guideline summary

NICE did not search for research specifically with Aboriginal and Torres Strait Islanders.

Updated search (systematic)

No papers were identified in a search related to Aboriginal and Torres Strait Islanders and BPD.

Additional Question: Cost-Effectiveness of BPD Treatments

NICE Guideline summary

1. **Individual therapies** (see page 141 NICE guidelines): The systematic search of economic literature identified three studies that assessed the cost effectiveness of individual psychological interventions for borderline personality disorder. One study examined the cost effectiveness of CBT (Palmer et al., 2006). The results of this analysis indicate that CBT is unlikely to be a cost-effective option for people with borderline personality disorder. Another compared the cost effectiveness of schema-focused cognitive therapy and transference-focused psychotherapy (Van Asselt et al., 2008). Overall, schema-focused cognitive therapy was less costly than transference focused psychotherapy over the 4 years of the analysis. The third study assessed costs incurred by people with borderline personality disorder before starting and after completing psychodynamic interpersonal therapy (Hall et al., 2001). Provision of psychodynamic interpersonal therapy to people with borderline personality disorder resulted in a net cost saving of AUS\$18,217 per person treated; when the intervention cost was raised to \$13,070 per person to reflect therapy provided by specialist psychiatrists, the intervention was cost saving only in the group of high users of healthcare resources.

2. **Combined treatments** (see page 150 NICE guidelines): NICE found no health economics studies on studies of combined psychological and pharmacological interventions.

3. **Psychotherapy programs** (see page 172 NICE guidelines): The systematic search of economic literature identified two studies assessing the cost effectiveness of psychological therapy programmes for borderline personality disorder. The analyses by Brazier and colleagues (2006) are characterised by a number of methodological limitations and the studies upon which the analyses were based were of small sample and not well reported; the authors they suggested that DBT could be a potentially cost-effective intervention in people with borderline personality disorder. Bateman & Fonagy (2003) assessed the total costs of MBT with partial hospitalisation compared with treatment as usual. The findings indicated that MBT might be potentially a cost-effective option in the management of borderline personality disorder. However, economic evidence is very limited, based on data from one small RCT only, and characterised by great uncertainty as the results of probabilistic analysis indicate.

4. Therapeutic communities (see page 186 NICE guidelines): The systematic search of the literature identified two economic studies on therapeutic communities. Both studies were conducted in the UK. One study had a before-after design and examined costs associated with treatment of people with personality disorders at the Henderson Hospital (Dolan et al., 1996). Based on the study results, the authors suggested that if the reduction in psychiatric care usage was maintained in the years following treatment, then the cost of treatment at Henderson Hospital would be recovered in just over 2 years following discharge. However, they admitted that usage levels of psychiatric care in this population over time were unknown and further research was required to confirm the potential benefits of treatment at the Henderson in terms of expected future cost offsets. The other study was a cohort study examining two programmes for people with personality disorders at the Cassel Hospital (Beecham et al., 2006). The results of the study indicated that both programmes provided at the Cassel were potentially more effective and more costly than general psychiatric care. The two-stage programme seemed to be more effective than the one-stage programme at a similar cost. However, the study is characterised by a number of limitations, such as the small study samples and the differential attrition between groups over the follow-up period, which may have introduced bias, as acknowledged by the authors of the study.

5. Pharmacological studies (see page 296 NICE guidelines): No evidence on the cost effectiveness of pharmacological and other physical treatments for people with borderline personality disorder was identified.

Updated search

Summary

There were 2 studies that included cost effectiveness data in addition to those identified by NICE. They were of varying quality and caution is required in interpretation. One study (Pasieczny) found that DBT was more clinically and cost effective than TAU, although this study was of questionable quality and not well reported. The other study (Thunissen) looked at aftercare options and found that the use of booster sessions was less costly and more effective than reintegration training so no cost effective analysis was undertaken. The results suggest that use of booster sessions as aftercare would be more cost effective than reintegration training. Overall, taking into consideration the NICE findings and the updated search, it is difficult to make any firm conclusions about cost effectiveness of treatments for BPD and further research in this area is required.

Evidence tables

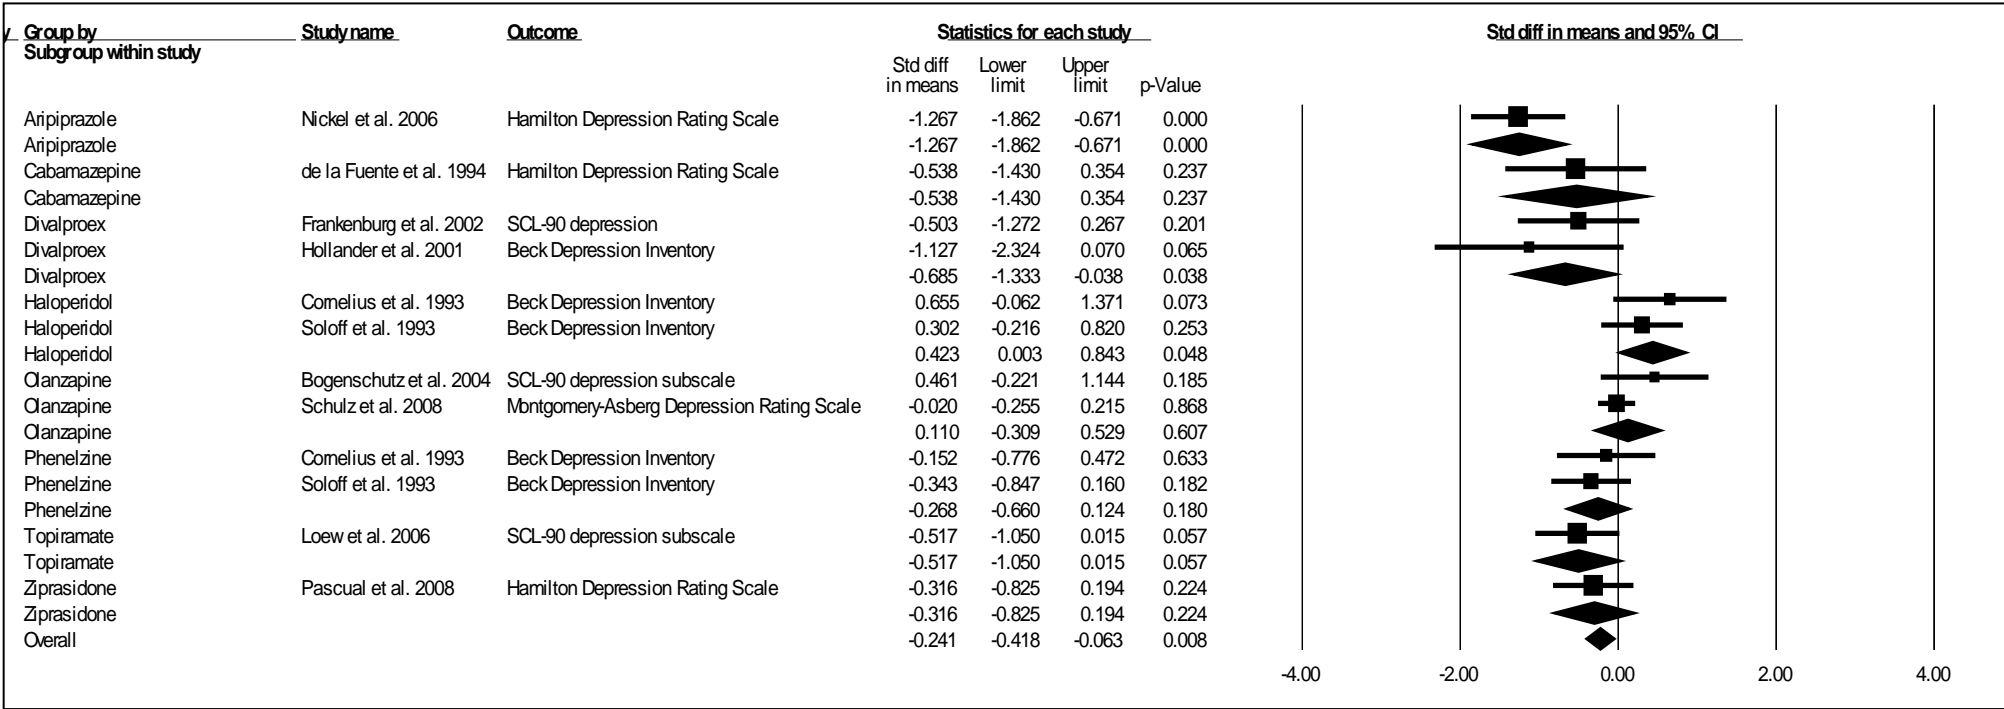

Figure 9: Effect of psychological treatments on depression

CBT: cognitive–behavioural therapy; DBT: dialectical behaviour therapy; DDP: dynamic deconstructive psychotherapy; MBT: mentalisation-based therapy; Std diff: standard difference; STEPPS: systems training for emotional predictability and problem solving; TFP: transference-focused psychotherapy.

Forest plot for meta-analysis of controlled psychological intervention studies that included depression as an outcome measure.^{1-4, 6, 15, 17, 24, 32, 33}

Figure 10: Effect of pharmacotherapy on depression

SCL-90: Symptom Checklist-90; Std diff: standard difference.

Forest plot for meta-analysis of placebo-controlled pharmacotherapy studies that included depression as an outcome measure.^{9, 12-14, 20-22, 25, 26, 30}

Figure 11: Effect of psychological treatments on anxiety

CBT: cognitive-behavioural therapy; DBT: dialectical behaviour therapy; MBT: mentalisation-based therapy; Std diff: standard difference; TFP: transference-focused psychotherapy.

Forest plot for meta-analysis of controlled psychological intervention studies that included anxiety as an outcome measure.^{1, 2, 6, 15, 17, 19, 24}

Figure 12: Effect of pharmacotherapy on anxiety

SCL-90-R: Symptom Checklist-90-Revised; Std diff: standard difference.

Forest plot for meta-analysis of controlled psychological intervention studies that included anxiety as an outcome measure.^{9, 13, 20-22, 30}

Figure 13: Effect of psychological treatments on suicidal ideation

DBT: dialectical behaviour therapy; MACT: manual-assisted cognitive therapy; Std diff: standard difference.

Forest plot for meta-analysis of controlled psychological intervention studies that included suicidal ideation as an outcome measure.^{1, 24, 31, 33}

Figure 14: Effect of psychological treatments on suicide and self-harm

CBT: cognitive-behavioural therapy; DBT: dialectical behaviour therapy; DDP: dynamic deconstructive psychotherapy; MACT: manual-assisted cognitive therapy; MBT: mentalisation-based therapy; Std diff: standard difference; TFP: transference-focused psychotherapy.

Forest plot for meta-analysis of controlled psychological intervention studies that included suicide/self harm as outcome measure/s.^{1-3, 6, 15, 16, 23, 24, 31-33}

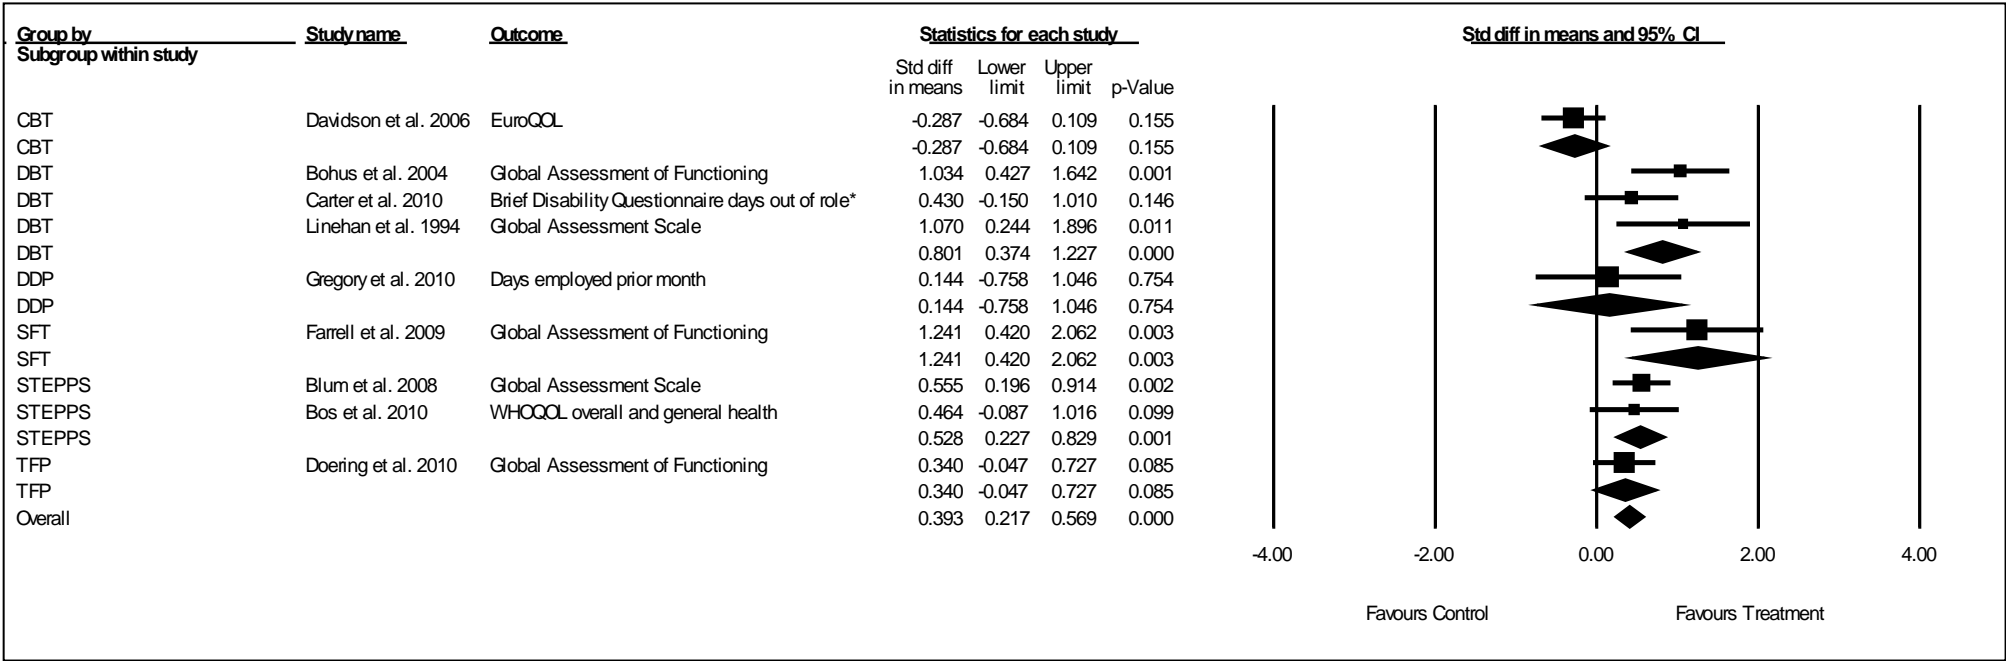

Figure 15: Effect of pharmacotherapy on suicide and self-harm

CGI BPD: Clinical Global Impression-BPD scale; Std diff: standard difference.

Forest plot for meta-analysis of placebo-controlled pharmacotherapy studies that included suicide and self harm as an outcome measure.^{11-13, 25}

Figure 16: Effect of psychological treatments on general functioning

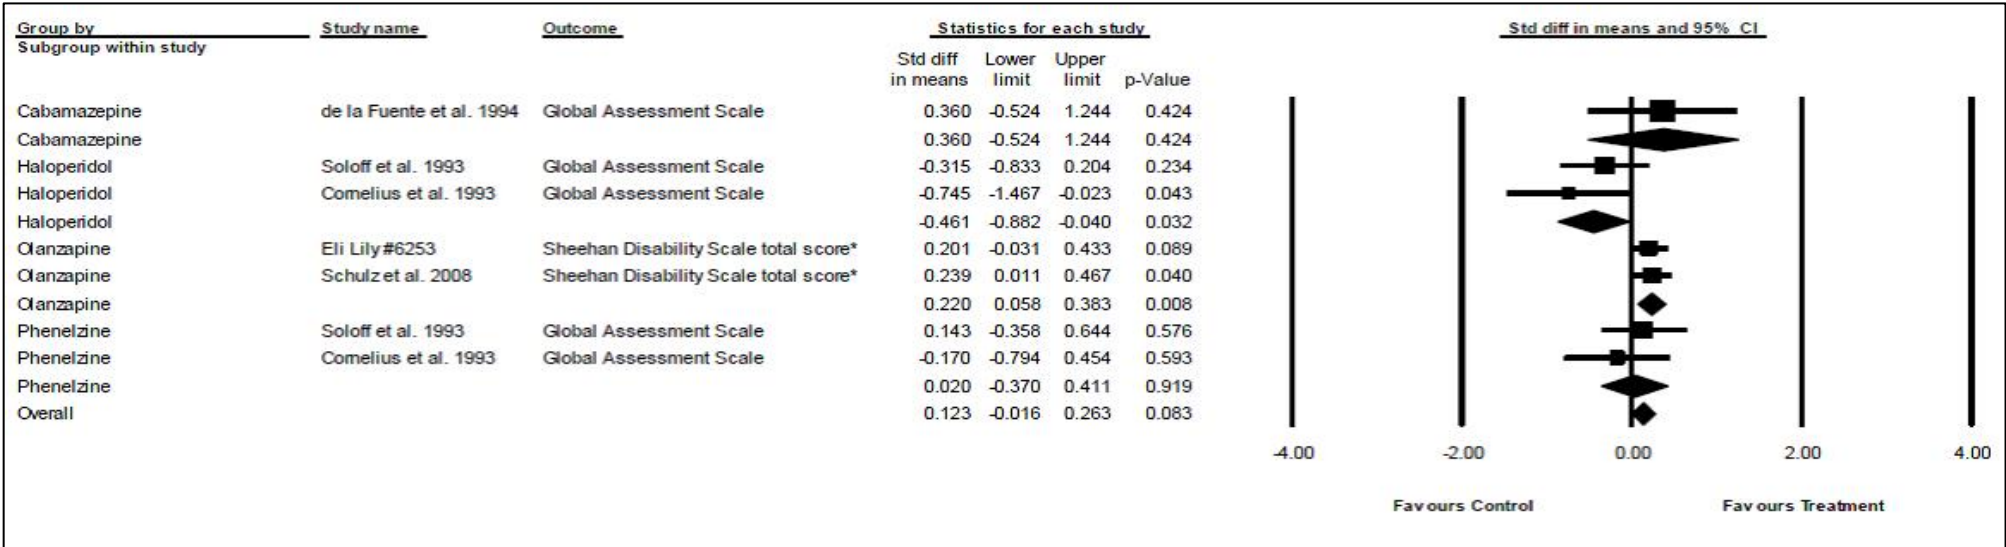

CBT: cognitive-behavioural therapy; DBT: dialectical behaviour therapy; DDP: dynamic deconstructive psychotherapy; EurQOL: EQ-5D (the EurQol Group quality-of-life assessment instrument); SFT: schema-focused therapy; Std diff: standard difference; STEPPS: systems training for emotional predictability and problem solving; TFP: transference-focused psychotherapy; WHOQOL: WHOQOL-Bref (the World Health Organization quality-of-life assessment instrument).

*Note: the effect size for Brief Disability Questionnaire was reversed for analysis

Forest plot for meta-analysis of controlled psychological intervention studies that included general functioning as an outcome measure.^{3-7, 15, 16, 19, 34}

Figure 17: Effect of pharmacotherapy on general functioning

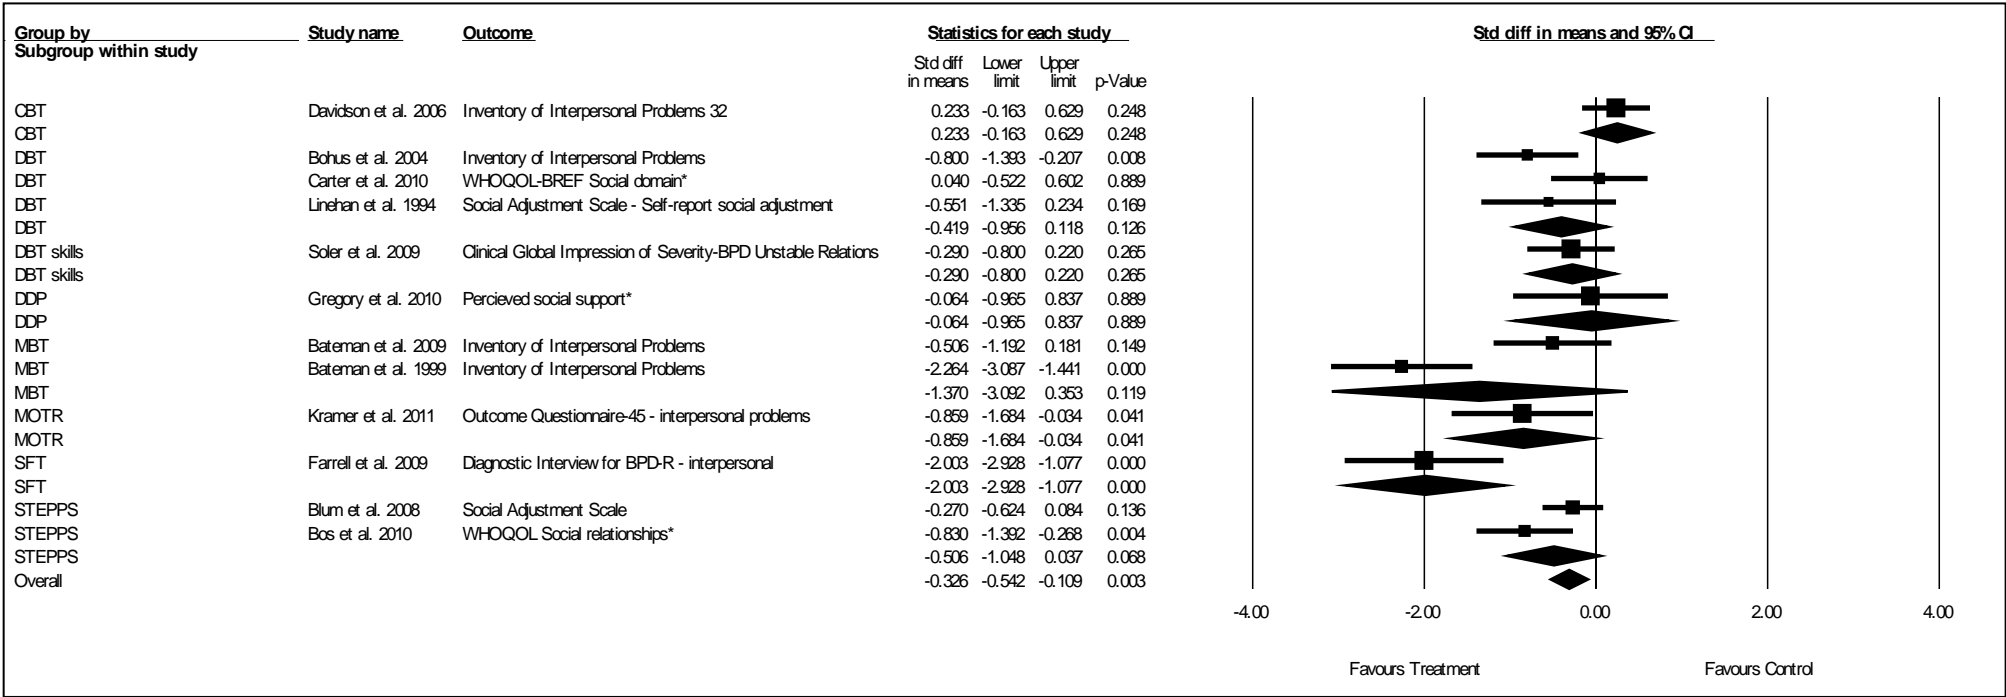

Std diff: standard difference.

Forest plot for meta-analysis of placebo-controlled pharmacotherapy studies that included general functioning as an outcome measure.^{9, 11, 12, 14, 21}

*Note: the effect size for the Sheehan Disability Scale total score was reversed for analysis

Figure 18: Effect of psychological treatments on social and interpersonal functioning

CBT: cognitive-behavioural therapy; DBT: dialectical behaviour therapy; DDP: dynamic deconstructive psychotherapy; MBT: mentalisation-based therapy; MOTR: motive-oriented therapeutic relationship; SFT: schema-focused therapy; Std diff: standard difference; STEPPS: systems training for emotional predictability and problem solving; WHOQOL: WHOQOL-Bref (the World Health Organization quality-of-life assessment instrument)

Forest plot for meta-analysis of controlled psychological intervention studies that included interpersonal and social functioning as an outcome measure.^{2-5, 7, 15-19, 32, 34}

*Note: the effect size for WHOQOL-Bref and Perceived social support was reversed for analysis.

Figure 19: Effect of pharmacotherapy on social and interpersonal functioning

CGI BPD: Clinical Global Impression-BPD scale; SCL-90: Symptom Checklist-90; SCL-90-R: Symptom Checklist-90-Revised; Std diff: standard difference.

Forest plot for meta-analysis of placebo-controlled pharmacotherapy studies that included social and interpersonal functioning as an outcome measure.^{11, 20-22, 26, 30}

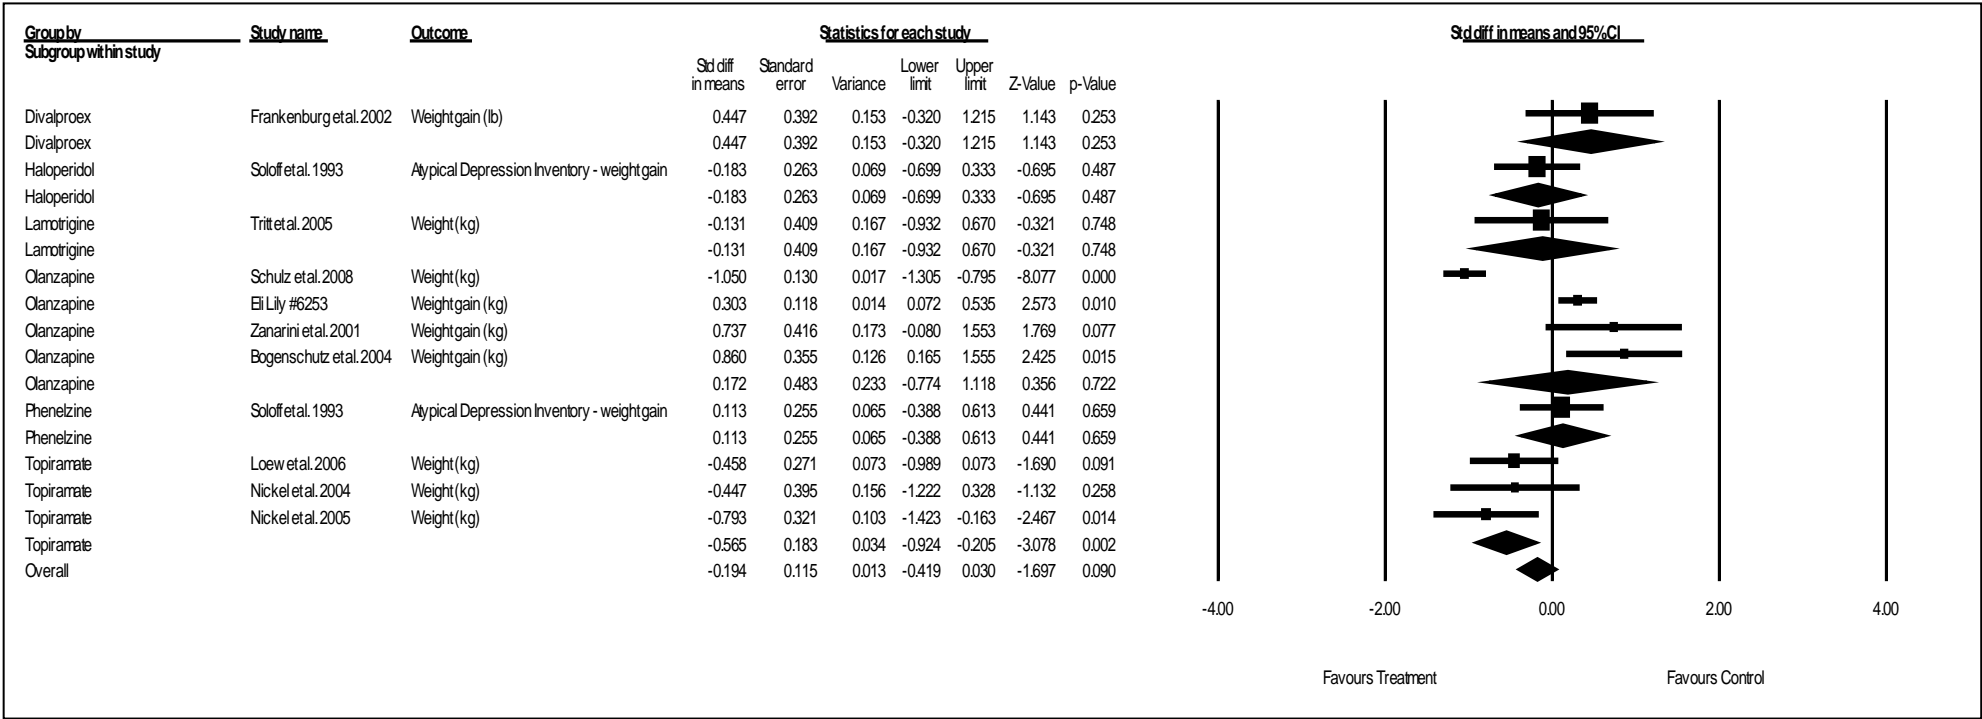

Figure 20: Effect of psychological treatments on hospitalisation

CBT: cognitive-behavioural therapy; DBT: dialectical behaviour therapy; MBT: mentalisation-based therapy; Std diff: standard difference; TFP: transference-focused psychotherapy.

Forest plot for meta-analysis of controlled psychological intervention studies that included hospitalisation as an outcome measure.^{6, 15-16, 24, 32}

Figure 21: Pharmacotherapy: Weight

Note: Favoursing intervention doesn't necessarily mean weight loss, it could mean that the gain in weight was not as large as the control group

Forest plot for meta-analysis of controlled pharmacotherapy studies that included weight as an outcome measure.^{9, 11, 12, 22, 26-30, 35}
